13. ABSTRACT (Maximum 200 Words) Army Experiment 4 (AE4) project was conducted by the Commanding General of the U.S. Army's Training and Doctrine Command (CG, U.S. Army TRADOC) during Fiscal Year 1997 (FY97). AE4 consisted of a series of experiments followed by a presentation at the Association of the United States Army (AUSA) convention in Washington D.C. 13-5 October, 1997. These were executed in an unclassified mode. The AE4 demonstrated a proof of concept for providing a seamless linkage between the simulations and the actual Command, Control, Communications, Computers, and Intelligence (C4I) systems that will be a part of Army XXI. The AE4 demonstrated "two way" C4I communications from division level down to the individual soldier level, and featured some advancement in automated capabilities. The primary schedule of events for support of the AE4 is provided in Appendix A of this document.

Army Experiment 4 (AE4); Army Battle Command Systems (ABCS); Command, Control, Communications, Computers, and Intelligence (C4I); Modular Reconfigurable C4I Interface (MRCI); Run Time Manager (RTM); Tactical Simulation Interface Unit (TSIU); Appliqué Interface; Medical Situational Awareness and Control (MSAC); Vehicle Health Monitoring System (VHMS).

1. AE4 Overview

Army Experiment 4 (AE4) project was conducted by the Commanding General of the U.S. Army's Training and Doctrine Command (CG, U.S. Army TRADOC) during Fiscal Year 1997 (FY97). AE4 consisted of a series of *experiments* followed by a *presentation* at the Association of the United States Army (AUSA) convention in Washington D.C. 13-15 October, 1997. These were executed in an unclassified mode. The AE4 demonstrated a proof of concept for providing a seamless linkage between the simulations and the actual Command, Control, Communications, Computers, and Intelligence (C4I) systems that will be a part of Army XXI. The AE4 demonstrated "two way" C4I communications from division level down to the individual soldier level, and featured some advancement in automated capabilities. The primary schedule of events for support of the AE4 is provided in Appendix A of this document.

1.1 AE4 Background

This paper provides a discussion on the results of the Army Experiment 4 (AE4) experiments which were executed 4 August through 5 September 1997. During the AE4 experiments, interfaces between various simulations and Army Battle Command Systems (ABCSs) were evaluated. Three separate experiments were performed to study various aspects of digitization of the battlefield: A Corps Battle Simulation (CBS) experiment, a Corps Level Computer Generated Forces (CLCGF) experiment, and a Dismounted Battlespace Battle Lab (DBBL) experiment. These experiments overlapped sufficiently to provide "two way" information flow from the division down to the individual soldier level. Discussion of the following simulation to ABCS interfaces is provided: The Run Time Manager (RTM), the Modular Reconfigurable C4I Interface (MRCI), the Tactical Simulation Interface Unit (TSIU), the Simulation Support Modules (SSMs), The Federation of Intelligence, Reconnaissance, Surveillance and Targeting, Operations, and Research Models (FIRESTORM)/High Resolution Simulation Stimulator (HRSS) simulation, the MITRE ModSAF Appliqué Interface (MMAI), and the Land Warrior System command and control interface to Appliqué. Additionally, discussion is provided on the Medical Situational Awareness and Control (MSAC) System, the Vehicle Health Monitoring System (VHMS), and Command Forces (CFOR).

1.2 AE4 Execution

The Army Experiment 4 (AE4) coordination, integration, and some development activities were performed under the U.S. Army Simulation, Training, and Instrumentation Command (STRICOM) Advanced Distributed Simulation Technology (ADST) II contract. Lockheed Martin Information Systems and their subcontractors performed the AE4 ADST II contract tasks.

23 April 1998

The AE4 sponsor was the U.S. Army Training and Doctrine Command (TRADOC). Other participating organizations are listed in the following section and Appendix I.

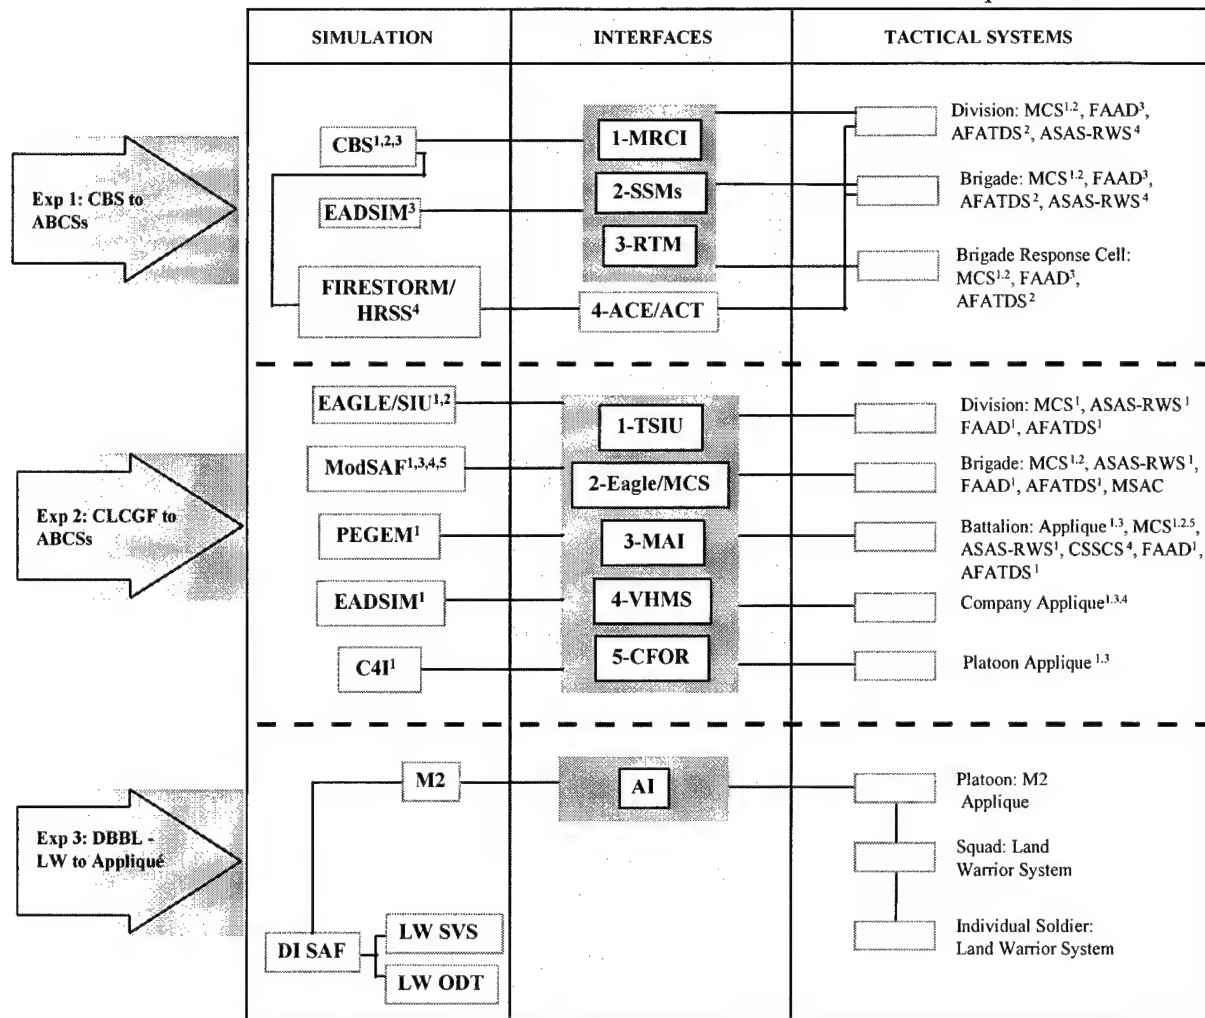

From 4 August through 5 September 1997, the AE4 team conducted a suite of experiments designed to create a working simulation that stimulated Army XXI tactical command and control (C2) systems from division level down to the platform/individual soldier levels. These experiments were broadly characterized as follows:

- Corps Battlefield Simulation (CBS) Experiment
- Corps Level Computer Generated Forces (CLCGF) Experiment
- Dismounted Battlespace Battle Lab (DBBL) Experiment

The AE4 experiment architecture is illustrated in Figure 1.2-1 on the following page. The AE4 experiment architecture was comprised of simulation systems, interface technologies, and Army Battle Command System (ABCS) components.

The AE4 experiments provided a baseline simulation and tactical interface environment, which provided valid and realistic insight into the linking of simulations with Army XXI C2 systems. These experiments were performed using a distributed simulation network (comprised of various simulations) and a separate tactical communications network (comprised of the Army Battle Command System (ABCS) version 2.0.4 (with patches) configured for each level of command). The simulation and tactical communications networks were interconnected utilizing various interfaces. These interfaces were evaluated for their potential for Warfighter training applications.

23 April 1998

Note: The coding scheme (i.e., 1, 2, 3, etc) is used to associate the simulation drivers, the interfaces, and the tactical systems (e.g., FIRESTORM feeds the ACE/ACT which feeds the Division and Brigade level ASAS-RWSs, etc).

Figure 1.2-1 AE4 architecture diagram for CBS, CLCGF, and DBBL experiments

1.3 Participating Organizations

TRADOC's Battle Lab Integration, Technology and Concepts Directorate (BLITCD) was responsible for the conduct of AE4. Lockheed-Martin Corporation (LMC) served as the primary systems integrator—under the direction of the Army's Simulation, Training and Instrumentation Command (STRICOM)—as part of the Advanced Distributed Simulation Technology II (ADST II) Program. The MITRE Corporation provided technical direction and consulting services, analyzed experiment results, and wrote an AAR.

The success experienced on the AE4 program was largely due to the strong teamwork among the organizations involved. The following organizations comprised the AE4 team:

Government organizations:

23 April 1998

- 1) Army Training and Doctrine Command (TRADOC)
- 2) Army Simulation, Training, and Instrumentation Command (STRICOM)
- 3) Army Dismounted Battlespace Battle Lab (DBBL)
- 4) Army Space and Missile Defense Command (SMDC)
- 5) Army Battle Command Battle Lab (BCBL) -- Fort Huachuca
- 6) Army National Simulation Center (NSC)
- 7) Electronic Proving Ground (EPG)
- 8) Program Executive Office Command, Control, and Communications Systems (PEOC3S)
- 9) Program Manager (PM) Air Defense Command and Control System (ADCCS)
- 10) PM Intel Fusion
- 11) Army Medical Research and Materiel Command (USAMRMC)
- 12) Army Aviation and Missile Command (AMCOM) Logistics Laboratory.
- 13) Soldier Support (Ft. Benning, Ft. Hood, Ft. Huachuca, Ft Leavenworth)

Contractor organizations:

- 1) Lockheed Martin Information Systems (LMIS)
- 2) Lockheed Martin Services Group (LMSG)
- 3) TASC
- 4) Aegis Research
- 5) Science Applications International Corporation (SAIC)
- 6) Mitre Corporation
- 7) Coleman Research Corporation (CRC)
- 8) Reality By Design
- 9) Hughes Aircraft Corporation
- 10) TRW
- 11) Cubic Applications Incorporated
- 12) Mystech
- 13) McGuire-Reeder Incorporated
- 14) Image Technical Services (ITS)
- 15) Mevatec Corporation
- 16) Booz-Allen Hamilton
- 17) Ulf Helgesson Industrial Design
- 18) Exhibit Crafts Inc
- 19) Soldier support for the AE4 was supplied by 4ID, Fort Leavenworth, Fort Sill,

TRADOC Analysis Command (TRAC) in Fort Leavenworth (while currently not officially tasked) provided outstanding support to the AE4 team. This support was greatly appreciated, and significantly contributed to the successful execution of the AE4 program

1.4 Problem Definition

Current studies indicate that the digitized force will increase military effectiveness and readiness. The digitized force requires two-way information flow from division to the individual soldier level, providing all echelons with an integrated, consistent view of situational awareness at their respective levels of command and control. Experimentation provides insight into some of the challenges facing digitization of the force by identifying potential cost-effective solutions that

23 April 1998

leverage investments in "Information Age Technology". The AE4 Program addressed some of these issues through a suite of experiments primarily aimed at evaluating the capabilities of simulations and simulation interfaces for populating Army Battle Command Systems (ABCSs) and using the data these tactical systems provide.

1.5 Objectives and Hypothesis

The AE4 experiment objectives focused on evaluating the interfaces that allow simulation systems to communicate with C4I systems; these form the key components in linking simulation systems to C4I systems. The intent was to assess the status of such interfaces in their abilities to support collective training, especially as they contribute to the reduction of exercise staffs and the improvement of training realism. The experiment-specific objectives of AE4 were:

1. Determine the extent to which the AE4 experimental hypothesis is true.
2. Determine the extent to which the experimental objectives, identified in the CBS and CLCGF experiment plans (included in the AE4 Technical Concept Plan), are met.
3. Provide observations, conclusions, recommendations, and lessons learned concerning the performance of the experimental systems (primarily the simulation to C4I interfaces), the simulations, the C4I systems, the communications infrastructure, and the experimental process.
4. Provide a set of residual capabilities that can have an immediate impact on the Army's ability to use simulation to support collective training.

The AE4 experiment hypothesis was as follows:

If a functional simulation/C4I architecture is developed that links constructive and virtual simulations to Army XXI C4I systems then soldiers can use it to practice Army XXI situational awareness on go-to-war Army Tactical Command and Control Systems (ATCSS).

The rationale for this hypothesis is that simulations can provide realistic input and response to C4I systems, allowing commanders and their staffs to train in their command and control processes without incurring the expense of sending large numbers of troops into the field.

1.6 AE4 Residuals

AE4 produced a number of residual, leave-behind capabilities. These residual products can be grouped into two categories: those with the potential for immediate, tangible impact on the way the Army conducts Situational Awareness training and those that are less tangible, relating indirectly to Situational Awareness training. Both are discussed in Appendix F.

1.7 Purpose and Organization of this Report

This AE4 After Action Report focuses on both of these objectives. It documents the observations, conclusions, recommendations, and residuals derived from the AE4 experiments and AUSA demonstration. It provides a permanent record of the AE4 project and its residual products, and serves as a resource for future work.

The remainder of this report is organized as follows:

23 April 1998

- Section 2 documents the AE4 experiments and observations;
- Section 3 reports on the AE4 presentation at the 1997 AUSA Conference;
- Section 4 discusses the planning and management that went into AE4;
- Section 5 provides a list of AE4 participants and points-of-contact;
- The Appendices provide details on the master schedule, experiment and presentation scenario, test plans, data collection, architecture, hardware, presentation scripts, residuals and participating organizations.

2. AE4 Experiments

Linking appropriate simulation systems to the ABCSs has potential for improving the ability to develop capabilities in echelon-to-echelon command and control, mission rehearsal, course of action analysis, unit training, and doctrine development. The AE4 program's purpose was to leverage investments made in synthetic environments, ABCS components, and the simulation interface technologies that facilitate inter-communication among them.

2.1 Overview of AE4 Experiments

From 4 August through 5 September 1997, the AE4 team conducted a suite of experiments designed to evaluate various simulations and interfaces to ABCSs. These experiments can be broadly characterized as:

1. Corps Battlefield Simulation (CBS) Experiment
2. Corps Level Computer Generated Forces (CLCGF) Experiment
3. Dismounted Battlespace Battle Lab (DBBL) Experiment

A three to four hour division level battlefield scenario was used as the basis for the experiments. The scenario used was a modified version of a portion of the Division XXI Advanced Warfighting Experiment (DAWE) that was to be conducted in November 1997. In the scenario, summarized below, the Fourth Infantry Division (4ID) fights a conventional battle in the early years of the 21st century.

***SCENARIO:** "The 4th Infantry Division executes a division attack west. 3rd Brigade is in the south executing the main attack. 2nd Brigade conducts a supporting attack in the north. 1st Brigade is the division reserve 30 to 40 kilometers behind and between the 3rd and 2nd. G2 notices enemy reinforcements being applied to the main objective area, weakening the area vicinity northern boundary. The Division Commander requests a boundary change from Corps to allow him to attack with the 1st Brigade to the north, leaving 2nd and 3rd Brigades to continue as planned. As the 1st prepares the replan, two issues must be addressed: 1) the logistics for a move north have not been planned, and the 1st must refuel before its attack and 2) there is a small village in the north area with an enemy emplacement that must be neutralized."*

The 4ID is the Army's Experimental Force (EXFOR) that has been equipped with prototypes of the Army Battlespace Command Systems (ABCS). These systems are expected to provide 4ID soldiers with enhanced situational awareness and the ability to plan and act quicker than their enemy. AE4 results provide insights on improving the ability of using simulations to stimulate

23 April 1998

C4I systems to train commanders and their staffs in the use of ABCS systems for improved situational awareness.

The AE4 experiment was composed of four phases: experimentation, data collection, data analysis, and documentation. The experiment was completed and data collected during the period 4 August through 6 September. Analysis of the data was performed in October and November, during which time the documented observations, conclusions, and recommendations appearing in this report were developed.

In the CBS experiment, two way information flow was demonstrated from the division to the battalion level. ABCS components representative of the following systems participated: WARLAB Tactical Analysis Center (TAC), Command and Control Vehicle (C2V) TAC, and the Battle Command Vehicle (BCV). In the CLCGF experiment, two way information flow was demonstrated from the division to the platoon level. ABCS components representative of the following systems participated: division TAC, C2V TAC, BCV, company level Appliqué, and platoon level Appliqué. Figure 2.1-1 below illustrates the echelon levels that were played, and the overlap of these experiments, such that complete two-way flow of information was simulated from the division to the individual soldier levels.

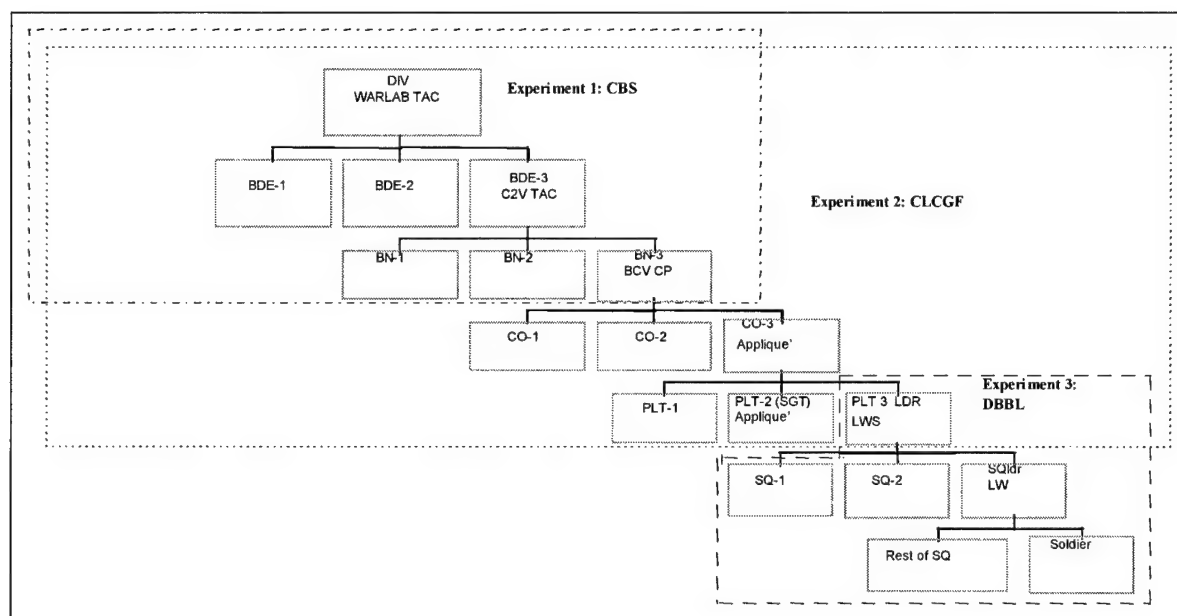

Figure 2.1-1 – AE4 experiment organization

2.2 Experiment Architecture

The AE4 hybrid architecture is composed of simulation systems, interface technologies, and ABCS components. The experiments were designed to exercise and evaluate the AE4 architecture components, with special focus on interface technologies that support “simulation to tactical system” linkages (see Figure 2.1-1). As part of the evaluation process, problems were documented with recommendations made for enhancements and future reuse. Each of the

23 April 1998

experiments is discussed in more detail in the following sections, with full test plans, component architectures, and data collection forms provided in the Appendices.

2.3 CBS Experiment

In the CBS experiment, the common battlefield scenario was executed from division to the battalion levels on Lantica terrain. The CBS experiment was run from 4-15 August 1997. The host site for this experiment was the Electronic Proving Ground (EPG) in Fort Lewis, Washington. Other participating sites included the Battle Command Battle Lab (BCBL) in Fort Huachuca, the WARLAB in Fort Leavenworth, and the Warfighting Analysis and Integration Center (WAIC) in Rosalyn, VA.

2.3.1 Objectives

A total of eight objectives were identified for the CBS Experiment, in addition to those established for AE4 as a whole:

1. Establish SSM benchmark to assess RTM and MRCI interfaces
2. Develop and document CBS experiment process
3. Assess MRCI capability
4. Assess RTM capability
5. Assess distributed, heterogeneous communication architecture
6. Capture experiment results for the AUSA demonstration
7. Document and publish experiment results and lessons learned
8. Provide feedback for future experiments.

The components assessed in the CBS experiments are briefly described in the following section, followed by a summary of observations organized by objectives.

2.3.2 Component Descriptions

The primary simulation-to-C4I tactical system interfaces evaluated were the Run Time Manager (RTM) and the Modular Reconfigurable C4I Interface (MRCI). These are summarized below:

- RTM. The RTM was used in conjunction with a CBS air and missile defense master interface, and Extended Air Defense Simulation (EADSIM), high fidelity/entity level simulation model providing CBS with air and missile defense interactions displayed on Forward Area Air Defense (FAAD) systems.
- MRCI. The Defense Modeling and Simulation Office (DMSO) has initiated the prototype development of the MRCI. For the AE4 program, the MRCI was integrated as an interface between CBS and Maneuver Control System (MCS) components and used to update CBS ground unit locations on the MCS boxes.

The following systems also participated in the CBS experiment:

- The integrated Federation of Intelligence, Reconnaissance, Surveillance and Targeting, Operations, and Research Models (FIRESTORM)/ High Resolution Simulation Stimulator

23 April 1998

(HRSS). The FIRESTORM/HRSS system allows users to focus, direct, prioritize and interpret the output of the larger Joint Information Environment, and provides intelligence data to the All Source Analysis System (ASAS).

- Analysis Control Team (ACT). The ACT is the hub of the Direct Support Military Intelligence Company capabilities. Tethered to brigade command post, it provides the brigade with intelligence connectivity, fusion, analysis and the ability to maintain the intelligence database. For the division level, an Analysis Control Element (ACE) is utilized which behaves similarly, but on a much larger scale. A single ASAS and Common Ground Station (CGS) workstation were used to provide a "slice" of the ACE functionality for the AE4.
- Corps Battle Simulation (CBS). CBS is a man-in-the-loop simulation that supports training of a corps commander and his battle staff, major subordinate commands, and major subordinate elements of headquarters of the corps in conduct of deep operations and decisive operations.
- EADSIM. EADSIM is a workstation-hosted, system-level simulation, which is used by combat developers, materiel developers, and operational commanders to assess the effectiveness of Theater Missile Defense (TMD), and Air Defense systems against the full spectrum of extended air defense threats.
- Simulation Support Modules (SSM's). The SSM's provide an interface between CBS and components of the ABCSs, and was be used as the benchmark for evaluation of the MRCI.
- ABCS Components. Section 2.1 identifies the ABCS components that participated in the CBS experiment, and illustrates the overall CBS experiment architecture.

The "leave behind" architecture for the CBS experiment is well-suited for use in the Training Exercises and Military Operations (TEMO) domain, especially in the area of staff level training. The AE4 CBS Experiment components are discussed in more detail in Appendix X.

The CBS experiment was a long haul exercise consisting of four different sites: Ft. Leavenworth (WARLAB); Ft. Lewis (EPG); WAIC; Ft. Huachuca Battle Tech Lab. The architecture for the CBS Experiment is depicted in Figure 2.5.2-1. Communication among the distributed sites consisted of a combination of the Army Interoperability Network (AIN) and dial-up modems. The distributed nature of the experiment components, coupled with the heterogeneous communication links, placed a high premium on pre-experiment integration and configuration procedures. LMC, in coordination with PEOC3S, provided on-site assistance during the system integration and checkout activities. A combination of telephonic and on-site technical support was available during the conduct of the experiment.

23 April 1998

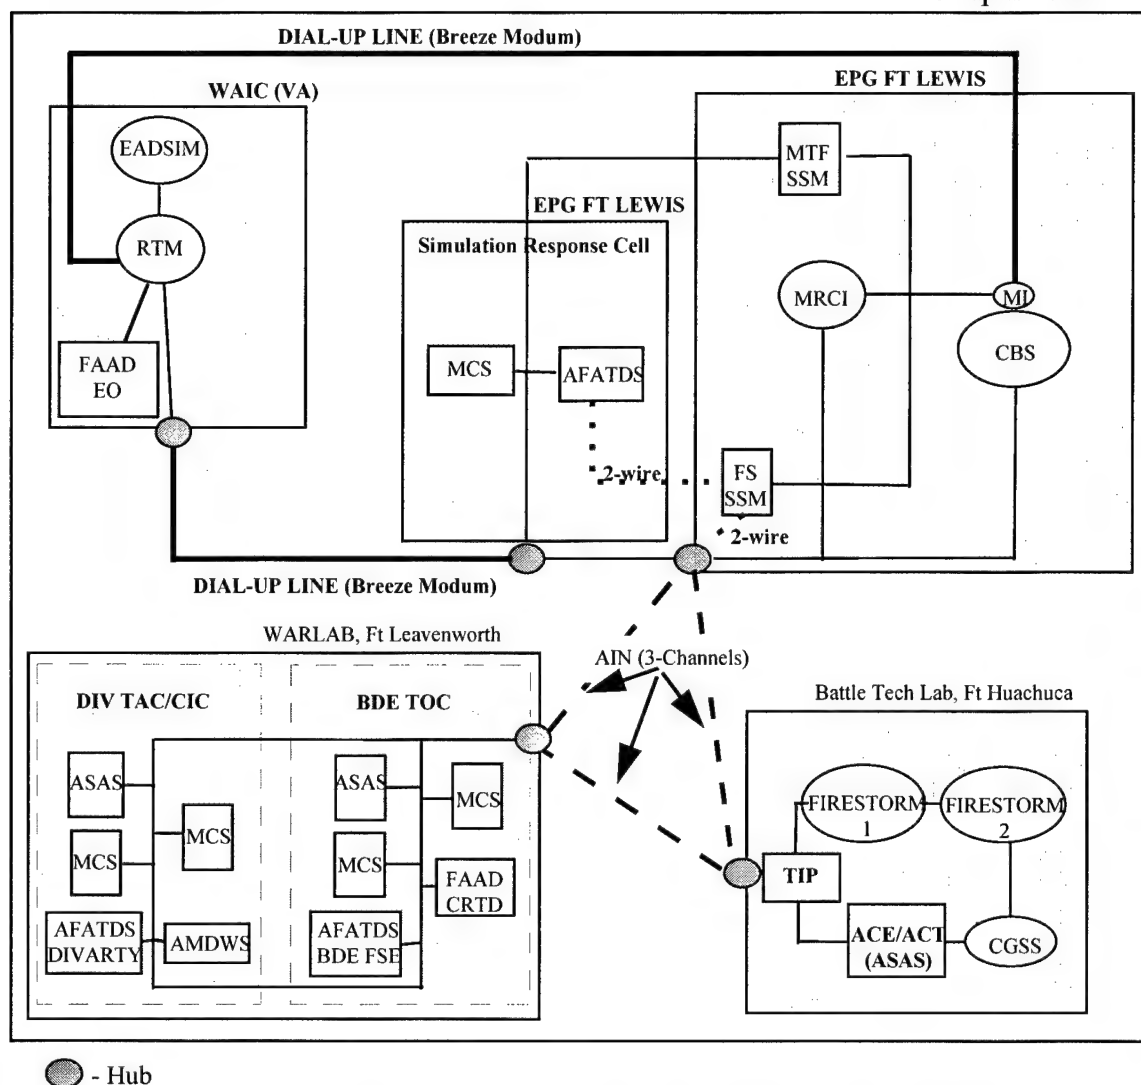

Figure 2.5.2-1 CBS Communications Architecture

2.3.3 Summary Observations and Findings by Experiment Objective

A total of eight objectives were identified for the CBS Experiment. It was envisioned that these objectives would support not only this experiment, but, with modification, could be used to support subsequent simulation-to-C4I system experiments within the Army. The summary observations, conclusions and recommendations relative to each experiment objective are presented below.

2.3.3.1 Objective 1 - Establish SSM Benchmark for Subsequent Interface Assessments

2.3.3.1.1 Observations

Benchmark functionality data were captured for the MTF SSM. Data captured included: friendly unit location and unit resource information; battlefield geometry; and enemy location information.

23 April 1998

The unit resource and battlefield geometry messages were received by MCS but did not auto-post to the MCS database. Manual entry by the MCS operator was required.

2.3.3.1.2 Conclusions

Changes in MCS releases necessitate updating the MTF SSM to ensure messages are processed correctly and posted to the MCS database. Since the unit status is normally sent by the CSSCS SSM, this functionality for the MTF SSM had not been updated for the version of MCS being used.

The battlefield geometry message contained too many segments, which prevented MCS from processing and posting the information. It was noted by the senior MCS operators that this segment overloading happens periodically, and the procedure is to send the information piecemeal (send fewer segments in each message).

2.3.3.2 Objective 2 - Develop and Document CBS Experiment Process

2.3.3.2.1 Observations

PEOC3S technical support was sporadic and lacked continuity during the system configuration and integration phases.

Funding for many participants was not forthcoming in a timely manner.

All data collection objectives to support analysis and report preparation were achieved.

2.3.3.2.2 Conclusions

Insufficient PEOC3S technical support necessitated modifications to original plans to meet experiment objectives. End result was a less robust experiment than envisioned.

Late funding hampered the planning and execution of the experiment, which exacerbated an already compressed schedule.

Extensive data collection and analysis efforts greatly increased credibility and validity of the experiment and this report. However, tools to support automated logging and analysis of experiment data would greatly increase the effectiveness and accuracy of future experimental analysis.

2.3.3.3 Objective 3 - Assess MRCI Capability

2.3.3.3.1 Observations

The MRCI experienced no problems interfacing with the CBS Master Interface (MI) and had no apparent intrusive effects on CBS.

The MRCI successfully extracted friendly unit location information from the CBS MI and sent the information to MCS. The information was processed and auto-posted to the MCS database at the battalion MCS located at Ft. Lewis.

23 April 1998

The friendly unit location information was not processed correctly (nor auto-posted) by either the division or brigade MCS located at Ft. Leavenworth.

The MRCI System Specific Interface (SSI) software must be loaded onto the MCS host platform.

There was a consistent round-down error in the last digit of the easting location field in each friendly unit location sent to MCS. Since the grid size was 100 meters, the MCS location reflected a 100 meter offset in easting location.

2.3.3.3.2 Conclusions

The functionality of the MRCI must be expanded significantly to achieve a level of functionality comparable with that of the MTF SSM.

The modular design concept for the MRCI is questionable, e.g., the loading of interface software on ATCCS platforms is not a preferred solution.

The opinion of one MCS technician at Ft. Leavenworth (who happened to be there for another meeting) was that the problem with MRCI information not being processed correctly by MCS was due to errors in one or more configuration files. Since both MCS and MRCI rely heavily on configuration files and there were no dedicated, on-site MCS personnel, it was not possible to isolate the problem.

2.3.3.4 Objective 4 - Assess RTM Capability

2.3.3.4.1 Observations

The RTM experienced no problems interfacing with the CBS MI and had no apparent intrusive effects on CBS.

The RTM was successful in de-aggregating air and TBM events extracted from CBS and then handing them off to EADSIM.

The RTM successfully provided all air and TBM messages to the appropriate FAAD systems.

The RTM provided TBM early warning messages to the AMDWS (located at Ft. Leavenworth) utilizing the extended FDL message set.

The RTM was able to send TADIL-B messages to the Tactical Communications Interface Module (TCIM), but the TCIM did not successfully transmit the messages to the FAAD EO.

2.3.3.4.2 Conclusions

The RTM provides increased training realism for FAAD personnel due to the representation of air and TBM events at the entity level vice the aggregated level provided by the FAADC2I SSM.

Additional resources are required to support the use of the RTM in CBS-driven staff training exercises, i.e., EADSIM and its associated support. On the plus side, the Army can conduct

23 April 1998

FAAD staff training, when desired, without Joint Training Confederation models such as the Air Warfare Simulation (AWSIM).

The design of the RTM interface to the CBS MI was effective and efficient for the volume of events contained in the experiment.

The RTM message flow to the FAAD EO system resulted in an accurate and timely low altitude air picture.

The capability of the RTM to send TADIL-B messages to the FAAD EO was not demonstrated due to the non-availability of a Digital Non-secure Voice Telephone (DNVT).

2.3.3.5 Objective 5 - Assess LAN and WAN Communication Architecture

2.3.3.5.1 Observations

The operational availability of the Army Interoperability Network (AIN) was outstanding for long haul connectivity.

There was a lack of ancillary items required to fully utilize the AIN voice and commercial/ISDN dial-in capabilities.

Trouble-shooting and data collection efforts were hampered due to the lack of a dedicated, open voice channel.

The DOIM personnel at Ft. Leavenworth and Ft. Huachuca were not able to configure the networks for an ATCCS environment and PEOC3S personnel were not available to provide network configuration support in a timely manner (par. 3.3.2.2).

Differences in ATCCS network configurations between the DAWE SIMEX I and the CBS Experiment created significant problems because technical support personnel were not familiar with the concept of the CBS Experiment, and hence the configuration needed (par. 3.3.2.2).

2.3.3.5.2 Conclusions

The AIN is a cost-effective, reliable alternative to the DSI for distributed experiments of this nature.

Continuous voice connectivity between experiment control personnel and data collectors at all sites is a must for trouble-shooting and synchronizing data collection efforts in a distributed environment.

Network support personnel must be identified and provided as part of the overall support package for experiments of this nature.

2.3.3.6 Objective 6 - Capture Experiment Results for the AUSA Presentation

2.3.3.6.1 Observations

23 April 1998

Screen captures, data, and lessons learned from the experiment were captured to support the AUSA Presentation.

Operators gained valuable experience that they carried forward to the remaining AE4 experiments and to the AUSA Presentation.

The AMDWS has more functionality than the FAAD CRTD.

2.3.3.6.2 Conclusions

The CBS Experiment provided valuable data and lessons learned on the RTM and MRCI interfaces, which also supported the AUSA Presentation.

Residuals from the CBS Experiment that were referenced during the AUSA Presentation are documented in Appendix X.

The AMDWS enhanced the training of division air defense staff personnel.

2.3.3.7 Objective 7 - Document and Publish Experiment Results and Lessons Learned

2.3.3.7.1 Observations

This report documents the results and lessons learned from the CBS Experiment.

Identification of those things that did not work as well as those things that did work are equally important in terms of residual value to the Army.

In a few instances, unqualified personnel were nominated by their units to support the experiment.

Operators were not adequately briefed on the objectives and scenario, nor were they fully aware of the sequence of events for the experiment.

2.3.3.7.2 Conclusions

The AE4 Reports published by BLITCD provided a good baseline data for future experiments.

The report-out philosophy for AE4 of including the failures as well as the successes help to identify areas for future improvement in interfacing C4I systems to simulation capabilities.

There is such a small pool of trained ATCCS operators within TRADOC that any requirement outside of the EXFOR is difficult to support. The problem in locating trained ATCCS operators is symptomatic of the current state of affairs in the Army - there aren't enough experienced ATCCS operators. The priority for trained ATCCS operators is the EXFOR (as it should be). However, institutionally the Army should be able to support other limited requirements for trained ATCCS operators.

23 April 1998

The lack of more operator involvement in the day-to-day discussions of the experiment must be counted as a lost opportunity. Those operators that have participated in these types of exercises or experiments can provide valuable insights and suggestions for improvement.

2.3.3.8 Objective 8 - Provide Feedback for Future Experiments

2.3.3.8.1 Observation

The CBS Experiment was an opportunity for the Army M&S and training communities, as well as interface developers, to gain valuable feedback for use in future experiments and development efforts.

2.3.3.8.2 Conclusion

This report provides insights, as well as being an excellent reference document, for use in planning and conducting future simulation-to-C4I system interface experiments.

2.3.4 Residuals

The "leave behind" architecture for the CBS experiment is well-suited for use in all three domains: Advanced Concepts and Requirements (ACR), Research, Development, and Acquisition (RDA), and Training Exercises and Military Operations (TEMO). It will readily accommodate test and evaluation activities, human factor studies, and other applications primarily due to features, which greatly reduce the manpower requirements for running an exercise. The CBS experiment Residuals are discussed in more detail in Appendix F.

2.4 CLCGF Experiment

In the CLCGF experiment, the common battlefield scenario was executed from division to the platoon levels on Lantica terrain. The Grafenfels terrain (a subset of Lantica) supported areas of operation where units were deaggregated down to the entity level. The primary simulation to C4I tactical system interfaces evaluated include the Tactical Simulation Interface Unit (TSIU), the Mitre ModSAF Appliqué Interface (MMAI), and the Eagle-MCS Interface. In addition, advancements made in logistics' Vehicle Health Monitoring System (VHMS), Medical Situational Awareness and Control (MSAC), and automated capabilities were evaluated.

In Appendix F there is a CLCGF comparison table with notes describing all the ATCCS and Applique interfaces tested.

2.4.1 Objectives

The primary objectives of the CLCGF experiment were the following:

- 1) Develop and document the CLCGF experiment process
- 2) Evaluate the various simulation/interface components:
 - a) Tactical Simulation Interface Unit (TSIU)
 - b) Medical Situational Awareness and Control (MSAC)
 - c) Vehicle Health Monitoring System (VHMS)
 - d) Mitre ModSAF Appliqué Interface (MMAI)
 - e) Eagle-Maneuver Control System (MCS) Interface
 - f) Command Forces (CFOR)
- 3) Assess the ability of the upgraded Defense Simulation Internet (DSI) to support a distributed simulation exercise

23 April 1998

- 4) Capture data to support the (CPSAA) at the AE4 Presentation at the AUSA General Meeting
- 5) Document and publish the Experiment results and lessons learned

2.4.2 Component Descriptions

The interfaces components and simulation systems used in the CLCGF experiment are summarized below.

- TSIU. The TSIU uses aggregated (Eagle) and deaggregated (entity level simulations) simulation data to provide simultaneous multilevel (i.e., division, brigade, battalion, company, platoon) feeds to tactical command and control systems. It provided a two way Variable Message Format (VMF) interface between command and control systems and simulations. Ongoing developments include modifications to allow VMF messages to be created from Signal Protocol Data Units (PDU's) and transmitted to Appliqué systems. These developments provided friendly force tracking, enemy force tracking (via spot reports), damage assessment, and Nuclear, Biological, and Chemical (NBC) data to Appliqué systems. The following automated features also were developed within the TSIU:

- 1) VMF "Call for Fire" messages were translated into CCSIL to be automatically executed by ModSAF.

- MMAI. The MMAI provided a two way VMF interface between Appliqué systems and simulations. The MMAI provided friendly force tracking, enemy force tracking (via spot reports), and battle damage assessments data to Appliqué systems.

- Eagle-MCS Interface. The Eagle-MCS was to provide a two way interface between the Eagle simulation and MCS. Unfortunately, the planned Eagle support necessary to execute this evaluation was not available during the test.

- MSAC. The MSAC serves as a command and control system for tactical medical operations, providing Situational Awareness (SA) data for friendly and enemy forces, and other data needed for medical operations, such as evacuation platforms, treatment facilities, and medical logistics. The MSAC used data from the simulation network to perform its functions, enabling the medical community to participate in real-time, combat simulation exercises.

- During the AE4 CLCGF experiment, the VHMS workstation combined the data received from the VHMS simulation and live VHMS module, and successfully populated the target Appliqué system with the required information. The live data was provided by a tank operating at Eglin Air Force Base. The Appliqué system performed a "roll-up" of the data received so that this could be passed on to the CSSCS. It is noted however, that the linkage between Appliqué and the CSSCS was not established due to database correlation problems. This was not a problem within the VHMS, but the target C4I systems, and is one example of the interoperability problems that can exist among ABCS systems.

- The VHMS experiment demonstrated a means by which the CSSCS can be utilized at the Battalion level (i.e. linking Appliqué to CSSCS). The use of the CSSCS at Battalion level is currently only a concept (generally, CSSCS supports the Brigade and Division levels), but may

23 April 1998

be worth consideration in the future given the logistical information that can be provided from Appliqué systems. Additional information concerning the VHMS can be found at the following web site address: <http://loglab.redstone.army.mil>

- Command Forces (CFOR). CFOR could not be evaluated to lack of SME support.

Other systems participating in the CLCGF experiment included:

- Eagle Simulation. Eagle is an aggregate level simulation designed for Corps level analytic work, but is capable of portraying any echelon in several environments. Eagle is a product of the Model Research Directorate (MRD), Training and Doctrine Command (TRADOC) Analysis Center (TRAC), Ft. Leavenworth Kansas. Eagle provides command and control functions that enable single operators to plan for and direct large numbers of aggregated entities on the simulated battlefield. Eagle models command and control (C2), maneuver, direct and indirect fires, helicopters, air defense, Close Air Support (CAS), and intelligence fusion.
- Simulation Interface Unit (SIU). The SIU is a product being developed by Science Applications International Corporation (SAIC) for TRAC Fort Leavenworth that is used to interface the Eagle Simulation with ModSAF. The SIU allows aggregated entities in Eagle to be selectively deaggregated into individual ModSAF entities. The SIU provides aggregate level simulation packets for units contained within Eagle (which is in addition to the entity level packets being provided by ModSAF). This allows Eagle units to be "ghosted" within ModSAF and for Eagle unit icons to appear on ModSAF Plan View Displays.¹ AE4 was the first full-scale use of the latest version of the SIU that was developed to interface with ModSAF Version 3.0. Although the SIU was a component of the simulation architecture for CLCGF and not an experimental system per se, a number of valuable insights into SIU functionality and the problems associated with combining aggregate and entity level simulations were made.
- ModSAF. Version 3.0 is the latest release of the ModSAF software. ModSAF is a United States Army Simulation Training and Instrumentation Command (STRICOM) product being developed by various contractors. ModSAF is a set of software modules and applications used to construct simulation and Computer Generated Forces (CGF) applications. ModSAF modules and applications allow a single operator to create and control large numbers of entities that are used for training, test, and evaluation. ModSAF entities, which include ground and air vehicles, dismounted infantry (DI), missiles, and dynamic structures, can interact with each other and with manned individual entity simulators to support training, combat development experiments, and test and evaluation studies.
- Post Engagement Ground Effects Model (PEGEM). PEGEM is an SMDC simulation that models NBC hazards based on post-engagement dispersal and propagation of the chemical cloud resulting from intercepting a TBM with a chemical warhead. Simulated sensors placed within the virtual environment can then detect the chemical cloud. PEGEM reports ground footprint

¹ As noted in Chapter 2, the SIU does not provide support for interactions (e.g. battles) between aggregated units and individual entities.

23 April 1998

centroids, and sensor warning messages (NBC-1), has real time event scheduling, and can independently score contaminated assets.

- The C4I Surrogate. The C4I Surrogate is an SMDC simulation that is used as a test driver to produce various types of "sensed" information from the simulation environment. It provides a low fidelity simulation source for the intelligence information feeds that would be received by the tactical C4I systems. Each simulated element has a radio and affiliated frequency that each model emulates when sending DIS Transmitter and Signal PDU's. The sensor models are unclassified and are written in Ada and C. The C4I surrogate runs on a Sun SPARC workstation utilizing the Solaris 2.5.1 operating system. It supports DIS protocol version 2.0.4, connects to the DIS network via Ethernet, and uses the UDP/IP protocol.

- EADSIM. EADSIM is a workstation hosted, entity based simulation developed for the U.S. Army Space and Missile Defense Command (SMDC) which allows users to assess the effectiveness of Theater Missile Defense (TMD), and Air Defense systems against the full spectrum of air and missile defense threats. It was originally developed as an analytic tool, and has a significant number of analysis aids and displays, as well as a robust post-processing report generation capability. Simulation models include the following: fixed and rotary wing aircraft, Theater Ballistic Missiles (TBM), cruise missiles, sensors (IR and radar), intelligence collection, satellites, C2 structures, sensor and communications jammers, communications networks and devices, and fire support. EADSIM can also represent a variety of ground support equipment (e.g. launchers, trucks, etc.) and generic noncombatants. EADSIM provides a many-on-many theater-level simulation of air and missile warfare, an integrated analysis tool to support joint and combined force operations, and a tool to augment maneuver force exercises at all echelons with realistic air defense training. Operational commanders, trainers, and analysts to model the performance, and predict the effectiveness of ballistic missiles, surface-to-air missiles, aircraft, and cruise missiles in a variety of user-developed scenarios use EADSIM.

- ABCS Components. Figure 2.1-1 above (middle section) identifies the ABCS components that participated in the CLCGF experiment and the overall CLCGF experiment architecture.

2.4.3 Observations and Findings by Experiment Objective

A total of five objectives were identified for the CLCGF Experiment. It was envisioned that these objectives would support not only this experiment, but, with modification, could be used to support subsequent simulation-to-C4I system experiments within the Army. The summary observations, conclusions and recommendations relative to each experiment objective are presented below.

2.4.3.1 Objective 2 - Assess the following simulation/interface systems:

- Tactical Simulation Interface Unit (TSIU)
- Medical Situational Awareness and Control (MSAC)
- Vehicle Health Monitoring System (VHMS)
- MITRE ModSAF-Appliqué Interface (MMAI)

23 April 1998

- Eagle - MCS Interface
- Command Forces (CFOR)

2.4.3.1.1 Observations

- The **TSIU** was assessed in its ability to utilize aggregated (Eagle) and deaggregated (entity level simulations) simulation data to provide simultaneous multi-level (i.e., division, brigade, battalion, company, and platoon) feeds to tactical systems, and in providing a two way Variable Message Format (VMF) interface between Appliqué' systems and simulations. The TSIU performed all tasks as intended.
- The **MSAC** was assessed in its ability to provide realistic training opportunities for medical support personnel. The MSAC serves as a command and control system for tactical medical operations, providing total Situational Awareness for friendly and enemy forces/objects such that Medical commanders and their staffs are challenged to make "real time" battlefield decisions with respect to route planning considerations, selection of available evacuation platforms and treatment facilities, and in providing medical logistics. A casualty generator is utilized to provide notification regarding casualties. As casualties are incurred, the medical support team executes their mission taking into account the data received by the MSAC system. In the CLCGF Experiment the MSAC performed all tasks as intended although full MSAC functionality was not integrated into the 2.0.4 version of MCS and the MCS Beta version was used as a surrogate. Details of the assessment of the MSAC are at paragraphs 4.3.1.4 through 4.3.1.6.
- The **VHMS** represented a concept for providing Situational Awareness for maintenance personnel for both training and real-world operations. The VHMS consists of two major components: a VHMS Module mounted on a live military vehicle, and the VHMS Workstation that is used to receive live data from the VHMS Module, model the function of the VHMS for simulated entities, and transmit the digital logistics data received to Appliqué and CSSCS systems. In the CLCGF Experiment VHMS was able to provide maintenance data from both live and simulated vehicles. Details of the assessment of the VHMS are at paragraphs 4.3.1.7 through 4.3.1.9.
- The **MMAI** provided a two way VMF interface between Appliqué' systems and the ModSAF simulation. The MMAI was actually a federation of simulations and interfaces based on the High Level Architecture (HLA). The MMAI development effort demonstrated the potential of the HLA to provide a framework for integrating C4I systems with simulations. The baseline capability was extended by introducing realistic communications effects. Assessment of the MMAI was limited due to resource constraints. However, the MMAI did demonstrate, among other things, an approach to provide a realistic simulation of communications effects for Situational Awareness training.

23 April 1998

- The **Eagle-MCS interface** is being developed under the joint sponsorship of TRAC (Fort Leavenworth) and Battle Command Battle Lab (Fort Leavenworth). Eagle-MCS is a two way interface between Eagle and MCS which can be used to pass operations orders from MCS systems to simulated Eagle units for execution, and populate MCS systems with simulation data generated by Eagle. Attempts were made to perform the integration of the Eagle-MCS interface into AE4 CLCGF experiment, however, it was determined that the Eagle-MCS interface (which was developed for version 7.0 of the MCS system) could not be integrated with MCS version 6.3 (the version being used to support the AE4 experiments). Thus, it was decided not to run the Eagle-MCS portion of the experiment.
- **CFOR** is a Research and Development effort being performed for the Synthetic Theater Of War (STOW) 97 program. This effort is being sponsored by the Defense Advanced Research Projects Agency (DARPA). The CFOR Command Element (CE) modules interface with ModSAF Version 3.0 directly via CCSIL. The purpose of CFOR is to model the command and control activities of the company-level unit commanders. Unfortunately, due to resource constraints it was not possible to get the CFOR CEs integrated into the CLCGF architecture. Therefore no assessment of CFOR was performed in AE4.

2.4.3.1.2 Conclusions

The simulation systems and interfaces examined in the CLCGF Experiment demonstrated a number of capabilities that have the potential to improve the Army's current ability to use simulations to support training in the use of Situational Awareness. For example, whereas current training simulations focus primarily on the intelligence and operations staff, simulation systems such as MSAC and VHMS augment current by enabling participation by the medical and logistical communities. Interfaces such as TSIU, MMAI, Eagle-MCS, and CFOR demonstrate approaches for: providing two-way flow of information between simulations and C4I systems, stimulating C4I systems with perceived truth instead of ground truth, and reducing the size of the support staff needed to run a training exercise. The SIU demonstrated an approach for combining aggregate and entity-level simulations into a single simulation federation.

2.4.3.2 Objective 2 - Assess the Defense Simulation Internet (DSI)

2.4.3.2.1 Observations

In previous AE's the DSI had not performed as well as other WANs such as the Interim Defense Research and Engineering Network (IDREN) that was experimented with in AE3. Problems with the DSI had included poor reliability, limited bandwidth, and difficulties scheduling DSI access.² However, in FY97 the DSI was scheduled to undergo a major upgrade to include new high speed routers and incorporation of an industry standard data protocol. Since it was desired to demonstrate a capability to incorporate live, virtual and constructive simulations in the

² Problems encountered with the DSI are documented in the AE3 After Action Report.

23 April 1998

CLCGF federation³ it was decided to use the M2 virtual simulator at the Dismounted Battlespace Battle Lab (DBBL) to represent virtual simulation and to link this simulator to the federation via the DSI. A DSI connection between the DBBL and STRICOM, using the upgraded system, was combined with a dedicated fiber optic line between STRICOM and the CLCGF test facility at the ADST II Operational Simulation Facility (OSF). In addition, it was planned to use the DSI to link the simulations running at the Advanced Research Center (ARC) in Huntsville (EADSIM, PEGEM, and C4I Surrogate) into the DIS federation at the OSF.

³ "Live" simulation involves the participation of live soldiers and real world equipment. A field training exercise is an example of live simulation. In the CLCGF Experiment, live simulation was represented by the live M1A1 tank linked to the VHMS simulation "Virtual" simulation means live soldiers using simulated equipment. Simulators such as SIMNET or CCTT are examples of virtual simulation. "Constructive" simulation means that everything is simulated - there are no live players, although there may be operators or controllers. Eagle, ModSAF and the other CLCGF simulations are examples of constructive simulation.

23 April 1998

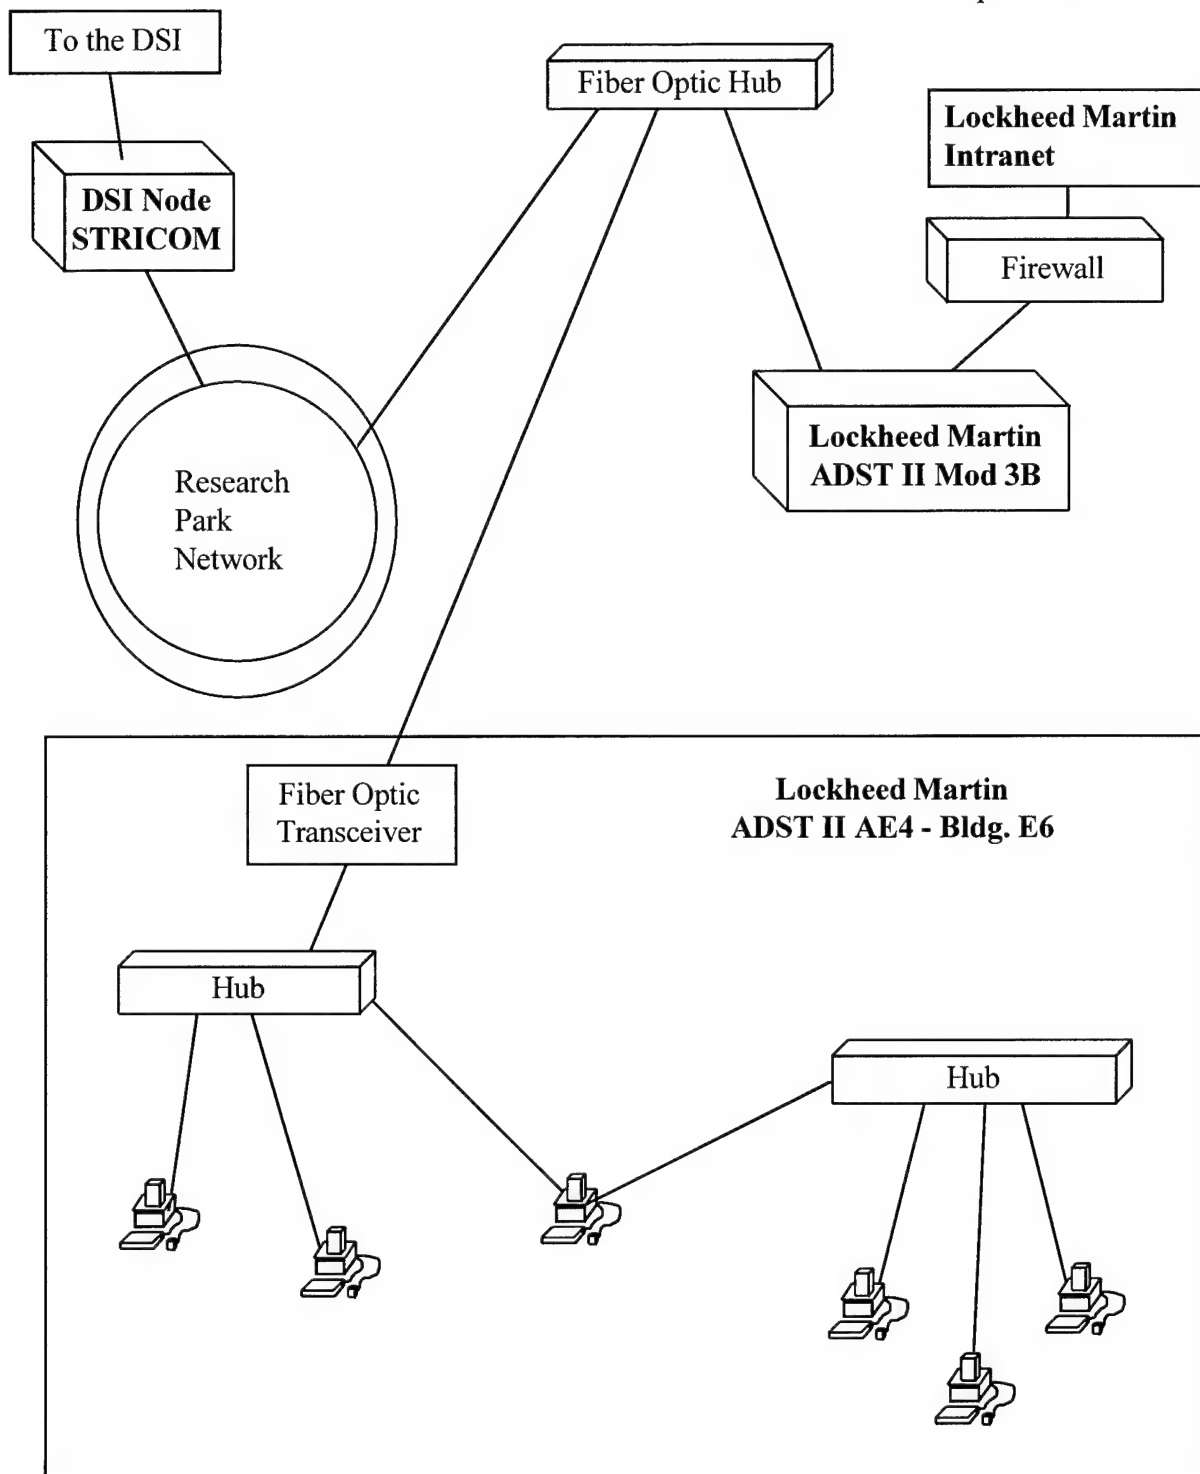

Figure 2.6.3.2.2-1 Long Haul Network

2.4.3.2.2 Conclusions

The DSI has tremendous potential for supporting distributed simulation experiments and exercises. The Defense Information Systems Agency (DISA), the agency responsible for the DSI,

23 April 1998

should evaluate the AE4 observations regarding the DSI to determine if they provide information that could be used to improve DSI performance.

2.4.3.3 Observation - Long Haul Connection

As discussed in paragraph 2.6.3.2 the connection between the DBBL, the ARC and the OSF was a combination of the upgraded DSI and a dedicated fiber optic line. The connection between the DSI and the fiber optic line was the Research Park Network (in Orlando), which includes as members both Lockheed Martin Information Systems, where the OSF is located, and STRICOM, which has a node on the DSI. When it was learned that it was not possible to exchange simulation data between the DBBL or the ARC and the OSF and exhaustive effort was undertaken to find the fault. Houston Associates supported this effort, the government's contractor responsible for administration and maintenance of the DSI. Although a number of problems were found and resolved during system integration and test, a connection was never successfully established prior to the start of the experiment period. At this point the personnel responsible for the ARC connection chose to replace the DSI with a Breeze Modem link. Further analysis determined that traffic was passing from the DBBL to STRICOM and from the OSF to STRICOM but was not crossing the bridge between the DSI and the leased line. Despite the best efforts of a number of network technicians, including a technician from Houston Associates, this problem was not resolved until the last day of the experiment. As a result, although the DBBL M2 virtual simulator was integrated into the CLCGF Experiment as planned, there was not sufficient time to collect data on the performance of the DSI or its impact on the overall experiment.

2.4.3.3.1 Conclusions

Since the DSI connection between the DBBL and OSF was not established until the last day of the experiment, it is not possible to draw any conclusions about DSI performance. However, it is a cause for concern that this connection failed despite extensive planning and the best efforts of a number of skilled technicians over a week's time. If the potential of the DSI is to be realized, it must be made more reliable and "user friendly". Through the debugging efforts at the OSF and STRICOM it was determined that the subnets were established incorrectly by Houston Associates, Inc.

2.4.3.4 Objective 3 - (CPSAA) Data Capture for AUSA

2.4.3.4.1 Observations

One of the systems included in the CLCGF architecture was a data logger (see Figure 4.1). This data logger recorded every PDU (including Signal PDU's) generated by the CLCGF simulations. The logger also recorded CCSIL message traffic. These PDU's and messages could then be used to replay any or all of the simulation events. After the experiment, PDU's representing the approximately three and a half hour scenario could be extracted as required to create the simulation events need for the twenty-five minute AUSA presentation. For the AUSA the TSIU was linked to the data logger to translate the Aggregate, and Signal PDU's and CCSIL messages and pass them to C4I systems.

2.4.3.4.2 Conclusions

23 April 1998

The success of the CPSAA presentation at the AUSA General Meeting is testimony to the validity of the approach used for CLCGF data collection. Further, it demonstrated a potential to use similar data collection methods, together with the TSIU's translation capability, to support After Action Reviews (AAR's) for training exercises. This potential capability is described in the AE4 AAR and is discussed in more detail in paragraph 4.3.3.

2.4.3.5 Objective 4 - Document Experimental results and lessons learned.

2.4.3.5.1 Observations

Previous AE's have been documented by an AAR similar to the one published by TRADOC for AE4. These AAR's have documented the AE process and many lessons learned but they have not, for the most part, been technically oriented. For AE4, it was decided that a systematic documentation of the technical observations and experimental residuals was required to ensure that potentially valuable information was not lost. This report is intended to meet that requirement. It complements the AAR by focusing on the technical observations and lessons learned. The two documents together provide a complete record of AE4.

2.4.3.5.2 Conclusions

This section of the AE4 Experiment report documents the technical observations, residuals and lessons learned in the CLCGF Experiment and places it in the context of the other AE4 experiments. Together with the AAR, it provides a complete record of the CLCGF Experiment.

2.4.4 Additional Observations and Findings

The observations summarized in paragraph 4.2 are presented in more detail below. The source of each observation is identified by use of the following codes: O - Operator; DC - Data Collector; TS - Technical Support Personnel; and G - General. The data collection sheets from the experiment are contained in Appendix E. The electronic data from the experiment is archived at the OSF.

2.4.4.1 Observation 1

The TSIU demonstrated a capability to stimulate a full set of ATCCS and Appliqué systems from the Division to Platoon level from both aggregate and entity level simulations.

During the CLCGF Experiment the TSIU demonstrated the capability to pass information from a variety of DIS simulations⁴ to the target C4I systems to include:

- Command and Control messaging (USMTF, VMF) to include:
 - blue force tracking(USMTF S507, VMF K5.01, CCSIL 201)
 - call for fire (VMF K2.04, CCSIL 401)
 - status reporting

⁴ The simulations were: ModSAF, EADSIM, and the C4I Surrogate. The TSIU was also able to extract data from the Eagle Aggregate PDU which was created by the SIU.

23 April 1998

- Air and missile defense messages to include:
 - high and low altitude air picture (TADIL-B, FDL)
 - early warning
 - TBM
 - NBC
 - NBC (NBC-1,4, USMTF C488, VMF K5.61)
 - TBM (predicted impact point – FDL F-59, FDL F-60, FDL F-61, FDL F-62, FDL F-63, USMTF C121)
- Intelligence data to include:
 - SPOT report (VMF K4.52)
 - RECCEXREPs
 - SALUTE report
 - Red Order of Battle
 - JSTARS MTI
 - telemetry (UAV/JSTARS position)
 - TBM (estimated launch point, pairing with impact point)
 - TACELINT
 - ACE (USMTF S309)

2.4.4.1.1 Conclusions

The TSIU demonstrated a capability to stimulate ABCS systems at each level of command from Division to Platoon. Extrapolating from its performance during the experiment, it appears that the TSIU has the capability to adequately stimulate the full suite of ABCS systems *providing that the necessary data can be generated by the simulation(s)*. That is, it appears that the TSIU's functionality is limited only by the availability of data.

2.4.4.2 Observation 2 - TSIU "perceived truth" rather than "ground truth"⁵

The approach used by the TSIU to provide perceived truth versus ground truth was to extract data only from the DIS Signal Protocol Data Units (Signal PDU's) and from CCSIL messages generated either by ModSAF or the C4I Surrogate simulation.⁶ This approach extracts the information from the Signal PDU's or CCSIL messages as necessary. The TSIU's role is to perform translation of the data provided by the simulations into the appropriate C4I message protocol and route that data to the intended C4I system(s). In AE4, the TSIU demonstrated a

⁵ The meanings of "ground truth" and "perceived truth" are provided in paragraph 2.1.2.2.

⁶ The ability to extract data from ModSAF generated CCSIL messages was a new capability for the TSIU that was developed for AE4.

23 April 1998

capability to serve as an interface between a simulation federation, which included both aggregate and entity-level simulations, and the ABCS C4I systems. Examples of how the TSIU functioned with various simulations is provided below.

- The TSIU read Aggregate PDU's produced by Eagle and the SIU. These PDU's represented ground truth on the location and status of the aggregate units being simulated in Eagle. The TSIU passed these PDU's to the C4I surrogate, which was simulating the Tactical Operations Centers (TOC's) for the aggregate units. The C4I surrogate applied a conversion to these PDU's to represent the errors and uncertainty in real world data. The converted PDU's were then translated by the TSIU into the appropriate tactical message and sent to the intended C4I system.
- The TSIU read CCSIL messages created by ModSAF entities and translated these into tactical messages. These CCSIL messages represented perceived truth from the perspective of the sending ModSAF entity. For example, a SALUTE report from a ModSAF entity would include only those enemy elements that had been detected by that entity using the appropriate ModSAF detection algorithms. Those enemy entities that could not be detected due to range, intervening terrain, or other factors would not be included in the message.
- The TSIU read Signal PDU's from the C4I surrogate. The C4I Surrogate provided simulation of all of the critical units and entities, such as unit TOC's and intelligence assets, not represented elsewhere, in the simulation federation. The C4I Surrogate played the role of several simulation federates that would be required to represent those elements not played in the "core" simulations (Eagle and ModSAF). Data sent from the C4I surrogate for intelligence systems such as JSTARS and UAV was derived from the sensor models in the C4I Surrogate. Although these models were low fidelity, they were sufficient to demonstrate the TSIU concept for providing perceived truth.

As mentioned previously, the TSIU did not model communications effects. Since none of the CLCGF simulations modeled communications, no communications effects, such as delay of messages, was imposed on the information provided to the C4I systems. Under the TSIU concept, communications effects would be calculated by a communications simulation federate and then imposed by the TSIU. Since no such communications federate was available for the CLCGF Experiment, this concept could not be demonstrated.

2.4.4.2.1 Conclusion

The TSIU demonstrated a viable approach for incorporating perceived truth data into a simulation-driven exercise. This approach assigns specific roles to the members of a simulation federation. The role of the interface (TSIU) is: to provide translation between simulations data and tactical message protocols, to route messages to the appropriate C4I systems, and to impose communications effects. The responsibility for providing perceived truth data to include the calculation of communications effects, rests with the simulations. The validity of this approach is dependent upon how well the simulations fulfill their role. It is beyond the scope of this report to conduct an analysis of the validity of the data provided by the CLCGF simulations. However,

23 April 1998

the data captured during the CLCGF Experiment is available to support such an analysis in the future. The TSIU did not impose communications effects on any of the simulation data because an appropriate communications model was not available. The MMAI did incorporate a communications effects model as described in paragraph 4.3.11. The MMAI concept for incorporating communications effects is very similar to the TSIU and indicates that the TSIU could have imposed appropriate communications effects had time and resources been available to integrate a communications model into the CLCGF federation.

2.4.4.3 Observation 3 - TSIU 2-way information flow (SIM/C4I)

Most of the data flow though the TSIU was one way from simulations to the C4I systems. Originally, enhancements were to be made to the TSIU to allow Appliqué operators to provide movement orders to simulated forces under their control. However, due to the aggressive AE4 schedule this feature could not be implemented in time. The requirements for performing this enhancement were sufficiently analyzed such that this feature could be added in the near future given available funding. The TSIU was enhanced to provide a translation of a VMF Call For Fire message (K2.04) generated at an Appliqué workstation to a CCSIL 401 message (Fire Request) for execution in ModSAF. During the demonstration it appeared that the translation was performed and the CCSIL 401 message was received at the ModSAF workstation; however, ModSAF did not react to this message. It appears that the problem was within ModSAF but the exact nature of the problem could not be determined.

2.4.4.3.1 Conclusion

It appears that the TSIU was able to successfully translate a VMF Call for Fire to a CCSIL message. Although a valuable capability, this is not a significant advance in the state-of-the-art since the VMF Call for Fire is a highly formatted message and other interfaces, such as the AFATDS SSM for CBS, have demonstrated similar capabilities. This is a potential task for future experimentation with the TSIU.

2.4.4.4 Observation 4 - MSAC Casualty Generator

ModSAF currently does not simulate personnel casualties. Thus, when a vehicle is damaged, there is no indication of the casualties incurred and, thus, no training opportunity for Medical commanders and staffs. The MSAC Casualty Generator is intended to address this deficiency. In AE4, detonation PDU's from ModSAF were read by the MSAC Casualty Generator which then determined the number and type of casualties via a probability table. Penetration, burn, and smoke inhalation casualties were modeled within the Casualty Generator and a Name, Rank, and Social Security Number (SSN) were assigned to support decisions regarding choice of medical treatment facilities, type of evacuation platforms, and other items of interest to the Medical commander.

2.4.4.4.1 Conclusion

Current versions of ModSAF do not represent casualties at a sufficient level of detail to provide training for medical support personnel. The MSAC Casualty Generator demonstrated an approach for adding this capability to ModSAF or other, similar simulations. By doing so, the MSAC has significantly increased the potential training audience that can be supported by simulation-based training. An important point is that the capability represented by the MSAC

23 April 1998

allows medical personnel to train alongside combat, combat support, and combat service support personnel in a realistic manner.

2.4.4.5 Observation 5 - MSAC integrated to MCS

The MSAC command module, integrated into MCS, demonstrated a capability to provide Situational Awareness to Medical commanders and staff.

The MSAC command module provides a map-based display with overlays, symbology, and other graphics capabilities to present red and blue force orders of battle, terrain details, routes, landing zones, and other data critical to Medical commanders. Using a Netscape implementation, MSAC allows users to click on various map icons to display the status of medical organizations at all levels of the battlefield to include medical treatment facilities, logistics, evacuation, and headquarters. Tools provided by MSAC gave Medical staff the ability to: task organize medical units with the capability to divert assets to critical areas of the battlefield, track all patients using digitized medical cards, and track the status treatments performed to virtual patients. Of the ten Medical functional areas, MSAC provided at least partial support for:

- Command and Control
- Evacuation (to include all ground and air evacuation platforms)
- Hospitalization
- Logistics, Blood, and Maintenance

2.4.4.5.1 Conclusion

In AE4, MSAC demonstrated the capability to expand Situational Awareness to include information of interest to Medical commanders and their staffs. This capability has the potential to improve the Medical decision-making process in the same manner that tactical Situational Awareness has for the maneuver commander. This capability, together with the Medical Casualty Generator described above also provides the opportunity to integrate medical personnel into training exercises with the rest of the staff. This not only enhances training for the Medical community but it also make training more realistic for maneuver commanders and their staffs. By introducing a requirement to include the planning for and implementation of casualty care, the MSAC adds an additional element of complexity and stress to the current training environment.

2.4.4.6 Observation - MSAC mounted on ATCCS 2.0.

Currently the MSAC has been fully integrated with the MCS/P beta version. As a "proof of concept" for AE4, a portion of the MSAC functionality was integrated into the Brigade level MCS baseline system (ATCCS Version 2.0.4). In the future it is anticipated that MSAC will be a module integrated as a part of CSSCS.

2.4.4.6.1 Conclusions

The MSAC demonstrated a capability to be hosted on representative ATCCS platforms. This indicates that it should be feasible to integrate the MSAC into a target system such as CSSCS without significant additional development work.

23 April 1998

2.4.4.7 Observation - Vehicle Health Monitoring System (VHMS)

One of the components of the VHMS evaluated in the CLCGF Experiment was the VHMS Module that is a Pentium based data acquisition tool located on the M1A1. at Eglin Air Force Base, FL. The VHMS Module collected data on the following vehicle parameters:

- Fuel
- Ammo
- Power train status
- Number 4 bearing oil scavenger temperature
- Number 5 and 6 bearing oil scavenger temperature
- Combustion gases temperature
- Temperature at the power turbine inlet

The temperature parameters were selected because they are indicators of potential catastrophic failures. The module recorded all parameter values in a database file. Whenever any of the parameter values exceeded a predetermined threshold or a given period of time elapsed the system sent the database file over a dedicated phone line via modem to the VHMS Workstation located at the OSF in Orlando. The VHMS Workstation, acting as a surrogate Appliqué, formatted a VMF Logistics Situational Report and forwarded it to the S1/S4 Appliqué at the Battalion TOC. The S1/S4 Appliqué combined this data with similar data from the other vehicles in the battalion, which were being played in simulation (see the discussion in the next paragraph), and forwarded a single Logistics Situational Report message to CSSCS at the Brigade TOC. The message is then incorporated in the CSSCS as Red, Green, Amber, or Black status for the weapon system. This alerts the CSSCS operator to a potential problem. The CSSCS operator can then use CSSCS's built in version of Netscape Navigator to query the VHMS for additional information. With this tool the operator can see which subsystem is causing the problems and drill down to the current status of the subsystem as well as a history for the subsystem. The intent of this capability is to provide maintenance personnel with near real-time information on system status to improve the timeliness of maintenance support and, potentially, to avert catastrophic failures by providing maintenance before the system fails.

2.4.4.7.1 Conclusions

Like the MSAC, the VHMS demonstrated a capability to support both training and operational applications. The intent of the VHMS, as demonstrated in the CLCGF Experiment, is to provide maintenance support personnel with detailed data on the status of each vehicle in a unit to support planning for and executing maintenance support.

2.4.4.8 Observation - VHMS simulation-based training

The connection from the Vehicle Health Monitoring System and the CSSCS was not tested end-to-end. The reasons for this activity could not be accomplished per the following paragraphs.

The VHMS interface was successfully linked to a live vehicle on a range at Eglin AFB and was able to exchange data from the VHMS to the tank and back. The information which the tank sent to VHMS was then successfully sent to an Applique which was configured in the Battalion S1/S4 role. The updates from the live vehicle successfully stimulated the Applique. The

23 April 1998

communication path from the Applique to the CSSCS could not be established initially during the experiment period.

The main reason for the failure of the communication link from Applique to CSSCS was a version incompatibility between the two systems. The Applique was integrated with ATCCS during the Task Force XXI DAWE. After this experiment the Applique interface to ATCCS was not utilized for future experiments, such as Division XXI AWE. The ATCCS systems used for the AE4 experiment were DAWE versions and could communicate successfully between the ATCCS. Since the Applique was not integrated with this new version of ATCCS, updates to the Applique and CSSCS databases were required.

During the course of updating the systems, time for the VHMS experiment ran out. After configuration of the Applique and CSSCS databases the two systems were able to communicate information concerning supply points. There was no time left to test the interface from the live tank through VHMS to the CSSCS. However since the Applique could communicate with the VHMS initially and after configuration the Applique communicated with CSSCS, it is believed that the linkage of live data through VHMS to CSSCS could have been accomplished given more time.

2.4.4.8.1 Conclusions

Like the MSAC, the VHMS demonstrated a concept for using simulation to train support personnel. The intent of the VHMS Workstation is to provide realistic maintenance data to maintenance support personnel to allow them to practice the management of maintenance support assets.

2.4.4.9 Observation - VHMS to populate Appliqué

While the VHMS interface communicated readily with the Appliqué the link between the Appliqué and the CSSCS was difficult for a variety of reasons. The major reasons for the difficulties encountered in the connection of the CSSCS with the Appliqué could be traced to incompatibility in databases between the systems. This problem was encountered in several instances during the CLCGF experiment. The major reason for the incompatibilities can be traced to the fact that the ABCS software utilized for the experiment was configured for the DAWE SIMEX 1. This exercise required a change in the Address Book and UTO databases. Since Appliqué did not play in this exercise the new addresses and databases on the ATCCS systems were not the same as those on Appliqué. This problem was resolved with changes to the address book and updates to the database. Another problem was the fact that CSSCS does item matching based on item description or nomenclature rather than item number. Therefore, if Appliqué lists an item as, "Tank, M1A1" and CSSCS has the same item in its database as "M1A1 Tank", CSSCS will not recognize the two as being the same item. This made the problem of reconciling the databases between Appliqué and CSSCS more difficult than if matching had been done using Line Item Numbers (LINS).

2.4.4.9.1 Conclusions

The difficulties encountered in passing information between CSSCS and Appliqué highlight the need in future exercises for a standard Address Book which does not need to be changed for each different experiment. Similarly, a standard means for referencing database items between tactical C4I systems, preferably using an established numerical system such as LINS, would

23 April 1998

reduce the possibility of database incompatibilities and make any incompatibilities that do occur easier to identify and remove.

2.4.4.10 Observation - MMAI interaction HLA & DIS federations

The MMAI was actually an HLA federation based on version 1.0.2 of the HLA Runtime Infrastructure (RTI). The MMAI federation comprised the following three federates:

- The C4I system federate was responsible for directly communicating with the Appliqué, including the physical connection. The C4I Federate includes software used for translating messages between VMF and CCSIL. VMF messages coming from the Appliqué were translated to CCSIL and sent through the RTI to the Simulation federate (described below). CCSIL messages coming from the Simulation Federate were sent through the RTI and translated to VMF by the C4I Federate.
- The Simulation Federate software includes two basic components: the Simulation Interface that consists of CFOR client software capable of exchanging CCSIL messages; and the RTI Interface. The Simulation Federate also included a Position Server (PS) that was responsible for providing Situational Awareness data by realistically updating the positions of friendly entities. The PS simulation maintains the positions of friendly entities and the topology of the network structure based on the roles of the entities involved. The entity positions were obtained by subscribing to the Entity State PDU's published by the DIS federation. The PS simulation is a set of algorithms for determining when position reports are to be generated each of the friendly entities. The algorithms are based on the SA reporting scheme of the real Tactical Internet (TI). The PS simulation and server interface component are linked together within a single process.
- The Communications Effects Server (CES) is responsible for controlling the computation and application of the communications effects. It is considered the hub for the C2 message traffic within the architecture. The concept is that all C2 messages will pass through the CES federate on the way to their respective destinations. The CES federate is described in more detail in paragraph 4.3.1.11 below.

The MMAI federation interfaced with the CLCGF simulation architecture, a DIS federation, using DIS PDU's and CCSIL messages.

2.4.5 Conclusions

The CLCGF Experiment was one of the first demonstrations of an interaction between HLA and a DIS federations. This is important because of the mandate that all new simulations for the Department of Defense (DOD) be HLA compliant. By linking the MMAI to the CLCGF DIS federation, the CLCGF Experiment showed that an HLA federation can interact with a legacy, non-HLA compliant DIS federation through the use of appropriate interfaces or translators.

2.4.6 Recommendations

Evaluate the approach used by the MMAI to interface with the CLCGF DIS federation to determine if it has application for the development of WARSIM and other new simulations.

23 April 1998

2.4.7 Observation - MMAI Communications Effects Server (CES)

The CES federate included a communications model that computed the communications effects based on the positions of the sender and receiver(s) and the intervening terrain. The communications model is referred to as the Communications Model Module (CMM). The CMM is a low fidelity model based loosely on the Tactical Internet (TI) scheme of communications. It combines deterministic and stochastic components to generate its results. Line of sight and propagation effects are computed deterministically using a terrain profile and the Terrain Integrated Rough Earth Model (TIREM). The network loading and delays associated with intranet communications in the TI are modeled stochastically based on System Performance Model (SPM) data generated by CECOM. The CMM does not explicitly model any of the radio systems found in the real TI. When a CCSIL message was generated by an entity in ModSAF or the MMAI Position Server generated a position report the positions of the sending and receiving entities were passed to the CMM. The CMM then performed the calculations necessary to determine if the message would be successfully transmitted. If the range or intervening terrain precluded communications, then the message was lost. In the case of position updates, the effect of lost transmissions could be seen on the Appliqué as vehicle icons changed color to indicate that the age of the information on their position had exceeded an acceptable value.

2.4.7.1.1 Conclusions

The loss of information due to communications effects is an important factor of the "fog of war". It is important for commanders and their staffs to learn to operate under realistic conditions of uncertainty. Many current simulations provide the training audience with information that is "too good" in part because the simulation does not incorporate communications effects. The MMAI CES demonstrated an approach for incorporating realistic communications into training simulations. The CMM was a fairly low-fidelity representation of the Tactical Internet and it did not incorporate some functions such as interference or jamming. However, it is not clear how much fidelity is "good enough" to accomplish meaningful training objectives. This issue should be addressed before developing more complex communications simulations.

2.4.7.2 Observation - MMAI free text orders Appliqué to ModSAF

The MMAI C4I Federate demonstrated a capability to translate simple, VMF free-text messages to CCSIL messages that were sent, via the CES, to ModSAF for execution. An operator on the company commander's Appliqué generated the free text messages. An example of the type of message that the C4I Federate could translate is, "First platoon move to checkpoint A". ModSAF would execute this message if: (1) the receiving entity (First platoon) had previously been assigned a movement route, and (2) that movement route contained a control point called "Checkpoint A". More complex messages such as, "First platoon move to a defensive position near checkpoint A", were not supported.

2.4.7.2.1 Conclusions

Most interactions between ground maneuver units occur as free text messages, often augmented by operations graphics. Current simulation-to-C4I system interfaces do not allow live players to send free text messages to units or entities within the simulation(s). Most systems currently require controllers to translate the messages generated by the training audience into a form that can be executed by the simulation. This approach increases the resources required to support a training exercise as well as increasing the potential for inducing errors in the simulation. In the

23 April 1998

CLCGF Experiment, the MMAI demonstrated a rudimentary capability that could be a first step in the development of interfaces that support true free text interactions between humans and simulations. There is still significant work to be done to refine this capability and expand it to include operations graphics. As was discussed above concerning the CES, it is not clear how much fidelity in free text interactions is required to support meaningful training objectives and this requirement should be defined before significant further development is undertaken.

2.4.7.3 Observation - ModSAF 3.0 Eagle/SIU

The SIU was originally developed to support the Joint Precision Strike Demonstration Advanced Concept Demonstration (JPSD ACTD). Subsequently, it was incorporated into the Joint Virtual Laboratory (JVL) at TRAC. It is a key component of the CLCGF architecture. The primary purpose of the SIU is to interface the Eagle and ModSAF simulations. It does this in two ways. First, it creates an Aggregate State PDU that is used to transmit to ModSAF information on the position and status of units being played at aggregate level in Eagle. This allows ModSAF to "ghost" those units. This means that ModSAF can display the location and movement of Eagle units but it does not control them nor can ModSAF entities interact directly with them. Secondly, it deaggregates Eagle units to individual entities that are then passed to ModSAF. When units are deaggregated, ModSAF controls the entities and these entities are able to fully interact with all other ModSAF entities. Furthermore, the SIU also passes to ModSAF the deaggregated unit's orders so that when the entities are created in ModSAF they know what to do.

The most recent version of the SIU was released just prior to the start of the CLCGF Experiment. This version had been developed to operate with ModSAF version 3.0, and was selected for AE4. Some problems were encountered with the operation of the SIU during the experiment. These problems were caused primarily by the fact that the software was new and relatively untested and that only limited technical support was available from the developer due to other commitments. The three major problems encountered are described below.

- Initial attempts to create the AE4 scenario were unsuccessful. The scenario was initially created in Eagle and ran without problem. However, when Eagle was linked to the SIU and ModSAF, the same scenario caused ModSAF to "crash" repeatedly. It was believed that the problem was incompatibility between the naming of unit and entity types between Eagle, the SIU, and ModSAF and the fact that ModSAF did not represent all of the systems in the AE4/4ID unit organization. Numerous attempts to resolve this problem were unsuccessful, primarily due to a lack of experienced technical support, and it seemed that the experiment would have to be run with older versions of ModSAF and the SIU. At the last moment the simulation developers at the JVL at TRAC volunteered to help solve this problem. Through their efforts, the incompatibilities between the simulations were resolved and alternatives were found for those systems not represented in ModSAF.
- The SIU was designed to perform deaggregation of Eagle under three sets of conditions: operator specified units could be deaggregated at game start, units could be automatically deaggregated when they entered a specified geographic area, or units could be deaggregated when they came within detection range of specified ModSAF entities. In AE4, only the first method of deaggregation was attempted. Once again,

23 April 1998

this was due primarily to the lack of dedicated technical support for the SIU. Without appropriate support it was considered too high risk to attempt "dynamic deaggregation" during the experiment.

- The SIU performed as expected when connected to an Eagle system to create aggregates and move these simulated entities about the battlefield. One feature, which has been used extensively in past experiments using the SIU, was the ability of creating aggregates directly on the SIU and moving these units via the ModSAF interface. This feature has been successful in rapid creation of scenarios in several previous exercises. With the new version of the SIU aggregates could be created on the simulated battlefield but could not traverse the battlefield. All efforts to solve the problem were unsuccessful.

Despite the problems encountered, the SIU successfully demonstrated an important capability; the linking of aggregate and entity-level simulations to represent different aspects of the same scenario. This capability allowed the AE4 scenario to be played at two different levels of resolution. The brigade that was used to stimulate the live TOC's in the experiment was played at the entity level of resolution while the rest of the units on the battlefield were "filled-in" by units played at a lower level of resolution in Eagle. This significantly reduced the simulation resources needed to support this division-level scenario.

2.4.7.3.1 Conclusions

The capability represented by the SIU is a potentially important one. Combining aggregate and entity-level simulations allows a training exercise to be developed that is tailored to the needs of the training audience. That is, those elements of the scenario that are of high interest to the training audience can be played with higher resolution at the entity level while those elements of less importance can be played at an aggregate level. Playing units at an aggregate level reduces scenario set up time and data requirements and, thus, the resources required to conduct an exercise. The SIU's capabilities were not fully demonstrated during the CLCGF Experiment due to the lack of dedicated technical support. This is a lesson learned for future experiments and exercises that appropriate technical support must be planned for all critical software items especially if they are new and relatively untested versions.

2.4.7.4 Observation - Eagle/SIU supporting unit deaggregation to entity level.

As described above, only one of three methods for unit deaggregation were demonstrated in the CLCGF Experiment. This method, the deaggregation of selected units at game start with no subsequent reaggregation, is called static deaggregation. This method was sufficient to support the tightly structured scenario used in the CLCGF Experiment. Scenarios used to support training exercises must be less structured to allow the evolution of the scenario to be dependent upon decisions made by the training audience. To support this type of scenario methods for dynamic deaggregation are required. Although the SIU is intended to support dynamic deaggregation, this capability was not demonstrated in AE4 for the reasons discussed above.

2.4.7.4.1 Conclusions

Dynamic deaggregation is a difficult problem that must be solved if aggregate and entity-level simulations are to be combined to support training exercises. This is particularly true in the case

23 April 1998

of ground maneuver units which, when deaggregated, must have each of their entities placed on the terrain in locations that are tactically reasonable and which must provide each entity with a set of tasks that will allow it to continue to perform the unit's mission. The SIU probably demonstrates the current state-of-the-art in dynamic deaggregation for ground maneuver units. It is unfortunate that the CLCGF Experiment was not able to assess the extent of this capability.

2.4.7.5 Observation - CPSAA presentation

During the CLCGF Experiment the data logger captured all of the PDU's and CCSIL messages generated by the simulations. For the CPSAA presentation a subset of this data was selected to provide playback of the events that were depicted in the CPSAA scenario, which represented approximately twenty-five minutes of the over three hour CLCGF scenario. As in the experiment, the PDU's and CCSIL messages were sent to the TSIU that created the tactical messages that were used to stimulate the ABCS systems during the presentation. The CPSAA presentation was a successful demonstration of a "playback" capability inherent in the CLCGF architecture.

2.4.7.5.1 Conclusions

The playback capability demonstrated at the CPSAA presentation represents a technique that would be valuable to use in a training AAR. The ability to replay an exercise and review the decisions made at each critical phase and the results of those decisions is a potentially valuable learning tool. The fact that this capability is supported by the same simulation/interface architecture that was used for the original exercise makes it that much more valuable. It should be relatively easy to expand this capability by including the ability to playback the exercise to a critical point and then "going live" with the simulations to investigate the impact of different decisions on the outcome of the exercise.

2.4.8 Residuals

The "leave behind" architecture for the CLCGF experiment is well-suited for use in all three domains: Advanced Concepts and Requirements (ACR), Research, Development, and Acquisition (RDA), and Training Exercises and Military Operations (TEMO). It readily accommodates test and evaluation activities, human factors studies, and other applications primarily due to automated/semi-automated features which greatly reduce the manpower requirements for running an exercise. Residuals are discussed in Appendix F.

2.5 DBBL Experiment

The AE4 DBBL experiment was held from 15 August - 5 September at Fort Benning, GA. In the DBBL experiment, the common battlefield scenario was executed from platoon to the individual soldier levels. The primary interface evaluated was the tactical communications linkage between Land Warrior (LW) systems and an Appliqué system mounted in an M2 Bradley Simulator. As a part of the experiment, actual LW equipment was integrated with the various participating Individual Combatant (IC) virtual simulation systems with the objective of replicating the LW capabilities in the virtual environment.

A key component for the DBBL experiment was the successful integration of the virtual component with the LW system. This capability enables IC virtual simulations utilizing the LW system to participate in large and small scale ABCS exercises by providing soldier level tactical

23 April 1998

communications connections to Appliqué systems. The scenario was executed on the Fort Benning Military Operations on Urban Terrain (MOUT) database due to the requirement for use of a high fidelity database to support typical, IC operations.

During the final week of the experiment the DBBL experiment was "linked" (with respect to tactical communications) to the CLCGF experiment. On the last day of the DBBL experiment, the M2 simulator and corresponding Appliqué system were re-initialized using the Grafenfels database, and attempted to participate as a part of the CLCGF experiment.

2.5.1 Objectives

A total of seven objectives were identified for the DBBL Experiment. The objectives included the following:

1. Evaluate the LWS C4I subsystem interface to both the DIS network and to Appliqué
2. Develop and document the DBBL experiment process
3. Observe the performance of the simulations/simulators and other support systems
4. Link M2 Simulator with Appliqué to the CLCGF Experiment
5. Perform data log and capture for the Association of the United States Army (AUSA) convention in October 97.
6. Document and publish results and lessons learned
7. Provide feedback for future experiments

2.5.2 Component Descriptions

The following systems were the primary components participating in the DBBL experiment:

- LW Omni-Directional Treadmill (ODT). The LW ODT consists of the following main components: an ODT locomotion simulator, the 3D simulation software, and a Walk In Synthetic Environment (WISE).
- LW Soldier Visualization System (SVS). The LW SVS allows unrestricted live soldier posturing for standing, kneeling, crouching, and prone positions. Movement is accomplished by means of a "joy stick" mounted on the rear of the user's LW weapon.
- Dismounted Infantry (DI) Semi-Automated Forces (SAF). DI SAF is an Army SAF (based on "leathernet" -- a SAF developed by the United States Marine Corps) which features firing positions such as prone, standing, and kneeling, and features standard infantry task behaviors.
- Appliqué Interface (AI). The AI is a residual product from the Force Protection Experiment (FPE) III held in Fall 1996 and is used to populate Appliqué displays with position data.

Note: No enhancements were made to this application for the AE4 program. The TSIU and MMAI (mentioned earlier) offered additional capabilities over and above the AI in their interface with Appliqué systems (e.g., red force tracking (via spot reports), the automated implementation of "movement orders", etc.).

- LW Interface. The LW interface provides linkages between the LW system and the 3D simulation software, thus enabling LW equipped IC virtual players to fire upon and laze

23 April 1998

simulated targets, communicate with Appliqué systems in a simulated combat environment, and perform other required IC tasks.

- The LW system was developed for the Program Manager (PM) Soldier program, and is the primary system used to provide IC tactical communications in the DBBL experiment.

2.5.3 Observation 1 – LWS to Appliqué

There were two LWS interfaces assessed in the DBBL Experiment: a tactical interface between the LWS and Appliqué, and a simulation interface between LWS and the DIS network. Regarding these interfaces:

- The LWS interface system successfully provided the VMF conversions required for a two way Land Warrior System linkage to Appliqué. During the beginning stages of the experiment there were a number of incompatibility problems between the LWS and Appliqué systems, but in the end these were resolved. SPOT reports were sent from the LWS system to Appliqué that resulted in enemy icons being displayed on the target Appliqué system. In return, as entities populated the Appliqué system, these were displayed on the LWS system. However, only a small subset of VMF messages could be passed between the two systems
- The LWS interface successfully provided the data required to link the LWS prototype weapon system with the 3D visualization software for enabling LWS soldiers to lase and fire upon simulated targets.
- When LWS or Appliqué reports positions, either, they represent “ground truth” directly from the simulation/simulator and do not accurately represent real world position or status reports.

2.5.3.1 Conclusions

The LWS interface demonstrated a good initial capability to interface the LWS with both Appliqué, thus providing a gateway into ABCS, and the DIS network, thus providing a gateway into future simulation exercises. The interface requires further development to make it more robust and to incorporate the full set of VMF messages. In addition, the PDU information could be modified to address “ground truth” limitations, perhaps by delaying messages, by means of a communications effects server, or adding “noise” to the PDU-supplied information to more accurately represent real world accuracy limitations.

2.5.3.2 Observation 2 - DI SAF

The DI SAF system performed reasonable well, but exhibited some anomalies in DI behavior.

The ODT/3D simulation system performed well, but is disconcertingly loud.

The SVS performed acceptably and had good stability.

The DI SAF, SVS, and ODT/3D simulation systems were linked together and demonstrated a potential capability to support infantry team training exercises.

The Appliqué system used in the experiment was actually Appliqué software mounted on a commercial laptop. This system proved to be very fragile and crashed often.

Soldiers had problems using LWS and Appliqué in the high-resolution DBBL scenario because of problems with maps of the McKenna MOUT site and surrounding area. Small scale maps of

23 April 1998

the area were not available for loading into the C4I systems, and the Appliqué and LWS maps are not scaleable. In addition, map downloads to LWS took almost half an hour.

Due to the timely and successful integration of the IC simulators, the visual system contractor took the initiative to fully integrate the Grafenfels database on both the SVS and ODT simulators. This offered additional residual benefit for the DBBL given that many of the current large scale digitization exercises are being performed in areas surrounding Grafenfels. However, it should be noted that the resolution of the terrain data in Grafenfels is not sufficient to support dismounted infantry requirements.

2.5.3.3 Conclusions

The DBBL Experiment demonstrated an ability to link heterogeneous virtual Dismounted Infantry (DI) simulators and DI SAF to conduct a platoon level dismounted exercise. This is representative of the type of capability that will be required by both the Army and the Marine Corps for training and mission rehearsal.

There is still noise within the user interface and control issues with the ODT/3D simulation software system.

Both Appliqué and the LWS are currently limited to a small number of pre-loaded or downloaded fixed-scale maps. During exercises or missions in a confined area, such as the MOUT used in these experiments, these maps will not provide the user with good situational awareness.

The SVS performed well, especially considering the relatively low cost of this PC-based system.

2.5.3.4 Observation 3 – Data Logger

An automated tool (Simulyzer) was used to build PDU log files from executing DIS simulation traffic. These PDU logs were then used to populate the Appliqué screens at the AE4 CPSAA presentation through the use of the TSIU as described in paragraphs 4.2.3 and 4.3.3. It was not possible to populate the LWS screen with simulation data at the CPSAA presentation because there were not sufficient resources to develop a TSIU translator for the LWS. Therefore, representative LWS screens were shown at the presentation.

2.5.3.5 Conclusions

Applicable network traffic was successfully data logged for editing/playback for the CPSAA presentation.

As noted in previous paragraphs, the log files could have also been used in an after-action reporting mode using a stealth in a playback mode.

2.5.3.6 Observation 4

This report is intended to serve as the documentation of the results and lessons learned from the DBBL Experiment. As noted in paragraph 5.1.6, the data collection process for the DBBL Experiment was less formal than was the case for the CBS and CLCGF Experiments. To compensate for this, the observations included in this section were reviewed by a broad range of experiment participants to ensure that these observations are as objective and accurate as possible.

23 April 1998

2.5.3.7 Conclusions

Despite the somewhat informal nature of the data collection process, the observations included in this report provide a good representation of the results of the DBBL Experiment. Although detailed analysis of the experiment was not possible, the observations provided are of sufficient detail and objectivity to provide a basis for decisions on future system development and employment.

2.5.4 Residuals

The "leave behind" architecture for the DBBL experiment will support IC operations and tactical communications to the individual soldier level. It is well-suited for use in all three domains: ACR, RDA, and TEMO, and will readily accommodate test and evaluation activities, human factors studies, and other applications related to IC areas of interest.

Residual components that resulted from the Army Experiment 4 DBBL experiment are listed in the table below:

Table 2.8.5-1 DBBL Experiment Residuals

Residual Component	Recipient
SVS	STRICOM/DBBL
ASTi DIS Radio Network (6 stations)	STRICOM/DBBL
LWS integration with SVS and ODT simulators	STRICOM/DBBL
LWS integration with Appliqué	STRICOM/DBBL
Appliqué integration with SIMNET M2 simulator	STRICOM/DBBL
MOUT database integration with SIMNET M2 simulator	STRICOM/DBBL

3. AE4 Presentation

3.1 Overview

The AE4 Presentation was held at the AUSA Conference in the Cotillion Ballroom of the Sheraton Hotel 13-15 October 1997 in Washington, D.C. The AE4 Presentation had two purposes: 1) to review results of the AE4 experiments held in August and September and 2) to preview situational awareness in a Full Spectrum Force XXI, focusing on seamless command and control from the division level to the individual soldier. The primary TRADOC messages for the AE4 presentation were the following:

- 1) SA is the key enabler for the Full Spectrum Force
- 2) Investment in Army XXI, the necessary foundation for Army After Next (AAN), is critical
- 3) There exists a large margin of improvement in SA for Division XXI

23 April 1998

The objective of the AE4 Presentation was to generate enthusiasm in visitors for what they saw in the theater and command post situational awareness area. The primary purposes of the presentation were to:

- 1) Chronicle the development and impact of changes in the technology of warfare that have had an impact on situational awareness and command and control;
- 2) Provide historical and background information on Force XXI processes;
- 3) Stimulate thinking about the value of situational awareness;
- 4) Provide a comparison of current "paper" means of maintaining situational awareness (e.g. maps) and Army XXI digitized means (e.g. ATCCS, Appliqué);
- 5) Provide background for the theater and CPSAA scenarios.

The physical layout and traffic flow for the AE4 Presentation is illustrated in Figure 4.

Visitor Flow

Figure 3.2-1 AE4 Presentation Facility Layout and Traffic Flow

The facility is composed of three major areas: the Reception Area, the Theater, and the Command Post Situational Awareness Activity (CPSAA) Area. Traffic flow is counterclockwise through the Reception Area, the Theater and the CPSAA Area. Each area is summarized below.

23 April 1998

3.2 Reception Area

The Reception Area (Figure 4, lower middle) consisted of a reception desk, a VIP start area, a timeline providing a graphic history of situation awareness along the front of the exhibit wall, and a CD ROM demonstration area. The historical timeline provided a chronicle for the development and impact of changes in the technology of warfare that have had an impact on SA and C2.

3.3 Introduction Theater Area

The Intro Theater Area (Figure 4, upper right) featured video presentations. The presentations were projected on three screens in a multi-media presentation. The video presentations provided a history of Force XXI (where we've been), explanation of the AE4 experiments (where we are), and insight into Army XXI systems which enhance SA (where we are going). The video presentations delivered the main message of a Full Spectrum Force ready for deployment to a wide variety of missions across the full spectrum of military operations. The special emphasis was on situational awareness in Army XXI as demonstrated in a common battlefield scenario. The video presentations provided an introduction to the main feature, the CPSAA.

3.4 Command Post Situational Awareness Area (CPSAA)

The CPSAA (Figure 4, left top) consisted of a gallery, and a stage area—where the experimental exercise is replayed to dramatically portray situational awareness in the Full Spectrum Force, and a CD distribution area at the front. The CPSAA was used to present Army XXI SA tools currently available to commanders and staffs from Division to the individual soldier level, demonstrate how Army XXI C4I systems and SA tools shorten and improve decision making process, and to illustrate how SA facilities dynamic execution of changed plans with minimal confusion in a battlefield scenario.

The stage area consisted of 6 booths representing the echelons of command from the division to the individual soldier level. The division was played by two role players with access to the division tactical systems exercised in the experiments, as outlined above. The Division level mock-up featured the 4th Infantry Division (4ID) Commander's Information Center (CIC). The brigade level was played using a C2V mock-up, with three live players who have access to equivalent tactical systems. The Battalion level was played by two live players in a mock-up BCV CP with similar systems. The Company level was played by a live company commander in an M1A1 mock-up with an FBCB2 system. The platoon level was played by a live Platoon Sergeant in an M2A2 mock-up with an FBCB2 system. A live Squad Leader dressed in land warrior equipment to include the land warrior system used for tactical command and control communications played the Individual soldier level.

As the scenario was initiated, the spotlight focused on the division commander, reviewing, on his tactical systems, the division's plan of attack. As the scenario progressed, he digitally requests a plan change of Corps based on new G2 of the enemy reinforcing his objective and leaving the northern border with weakened defenses. As the scenario unfolded, the spotlight moves from echelon to echelon highlighting the seamless digital flow of information critical to situational awareness for Army XXI. The command stream was followed down the command hierarchy,

23 April 1998

from system to system, and the report stream was followed back up the command hierarchy on the same systems.

A full script for the CPSAA is provided in Appendix B.

3.5 Demonstration Execution

3.5.1 Hotel and Union Labor

Lockheed Martin contracted with the Sheraton Washington Hotel and Greyhound Exposition Services (GES) for services required to prepare the Cotillion Ballroom for Army Experiment 4. These services included air conditioning, electrical power, telephone connections, network connections, tables, draping, and labor for installation, dismantling, and handling of equipment (unloading and loading trucks).

3.5.2 AE4 Teardown Pack and Ship

The planning for teardown packing and outbound shipping was discussed in detail during IPR's August and September. The final plan was executed on the last day of the demonstration, Wednesday 15 October, ITS began their strike at 4pm. The audio/video equipment was struck that enabled the ECI teardown team to breakdown the theaters. All AE4 ADSTII items were tagged for later inventory.

The day after the demonstration, Thursday 16 October, all equipment was packaged in its original crates or boxes. All equipment was crated and packaged in a safe and secure manner to prevent any damage during shipment. All Equipment was packed and not shipped loose. The equipment retained its original crate number for tracking.

3.5.2.1 HVAC

Lockheed Martin provided a cooling requirements analysis for both the Introduction Theater and the Command Post Situational Awareness Area. Based on that analysis, the appropriate cooling services were contracted with the Sheraton .

3.5.3 Power

Lockheed Martin provided a power requirements analysis for all elements of the AUSA. Based on that analysis, the appropriate power services were contracted with the Sheraton. The requirements were for three separate sources of power. The power distribution was discussed and planned for between Lockheed Martin engineering, Image Technical Services, Exhibit Crafts, and the Sheraton hotel services. The requirements were as follows.

- **Three Separate Power Sources (A, B, C)**
- (45) 110 VAC, 1ph, 20 amp Quad Outlets, NEMA 5-20 (Source A)
- (1) 220 VAC, 1 ph, 30 amp Outlets, NEMA L6-30 (Source B)
- (1) 220 VAC, 1 ph, 60 amp Outlets (Source B)
- (1) 220 VAC, 3 ph, 30 amp pigtail, (This is a Sheraton supplied A/C Unit used in the Intro Theatre; this is the same unit used in the October AUSA Demonstration 1996) (Source C)

23 April 1998

3.5.3.1 Telephone/DataFax

Lockheed Martin ordered and supplied dial-up telephone services and instruments from the Sheraton. There were two phone lines installed in the south side tech room area for voice and fax. ADST supplied a BROTHER FAX/Copier/Printer in the admin tech room and utilized this unit for administrative purposes. The analog instrument for the intro theater tech room phone #2 & #3 and the admin room phone # 14 was replaced with 900 MHz cordless phones. Figure 3.5.3.1-1 represents the distribution of analog telephone lines throughout the Cotillion Ballroom.

Figure 3.5.3.1-1 AE4 Telephone Distribution

Figure 3.5.3.1-2 depicts the AE4 demonstration distribution of the hand held 2-way radios. The radios were used religiously through installation, integration, demonstration and tear down.

Figure 3.5.3.1-3 AE4 2-Way Radio Assignment

3.5.4 Exhibit Support

3.5.4.1 Perimeter Drapes

Lockheed Martin arranged, through Greyhound Exposition Services (GES) the black perimeter drapes for a small section of the AUSA at the Cotillion Ballroom.

3.5.4.2 Furniture

Lockheed Martin arranged for all custom furniture to be designed and built by Exhibit Crafts Inc. Folding tables and chairs were provided by the Sheraton.

23 April 1998

3.5.4.3 Introduction Theater

Lockheed Martin arranged for, through ECI, based on designs received from the Exposition Conceptual Designer, an appropriate ramp and audience seating for the intro theater.

Lockheed Martin arranged for, through ECI, based on designs received from the Exposition Conceptual Designer, an appropriate enclosure for the intro theater.

3.5.4.4 Carpet

Lockheed Martin arranged for, through ECI, based on designs received from the Exposition Conceptual Designer, appropriate carpeting for the theater.

3.5.5 Audio Video Support

The audio/video (AV) support for the rehearsals and the demonstration was provided by Image Technical Services (ITS). The AV support was included in the Introduction theater and the Command Post Situational Awareness Area (CPSAA). The following figures illustrate the AV network diagrams. Figure 3.5.5-1 represents the Introduction theater AV network layout.

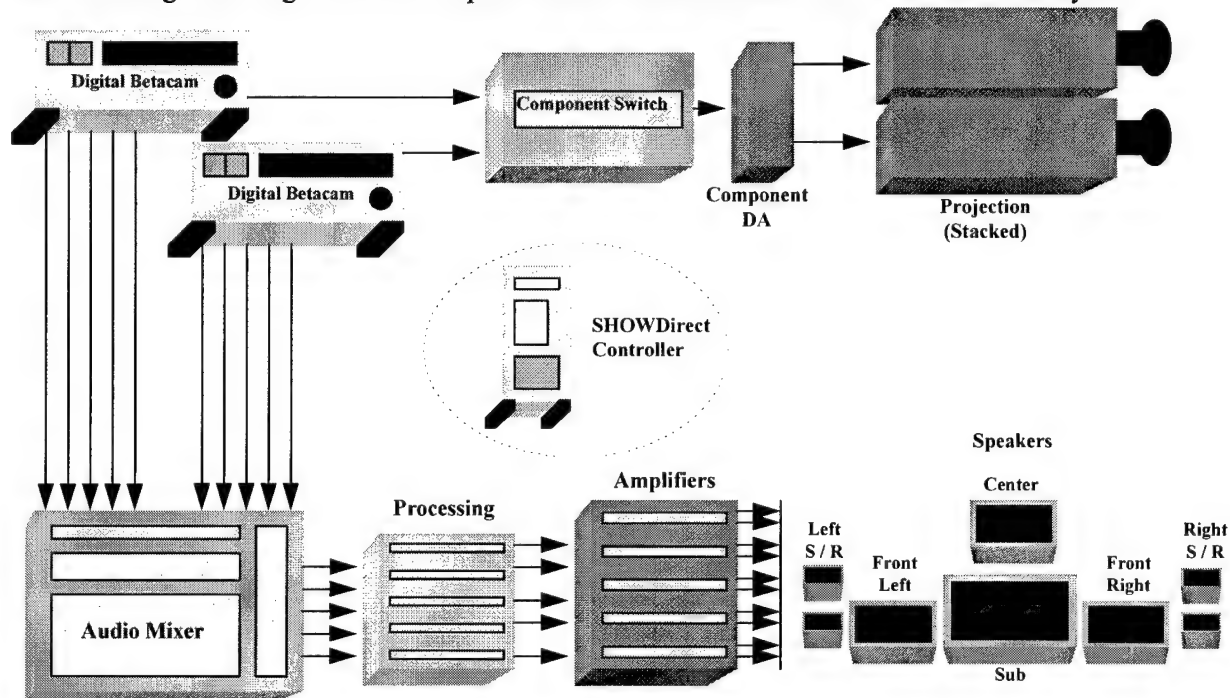

Figure 3.5.5-1 Introduction Theater AV Network Layout

The CPSAA AV is represented in figure 3.3.9-2.

23 April 1998

AE4 - CPSA Theater

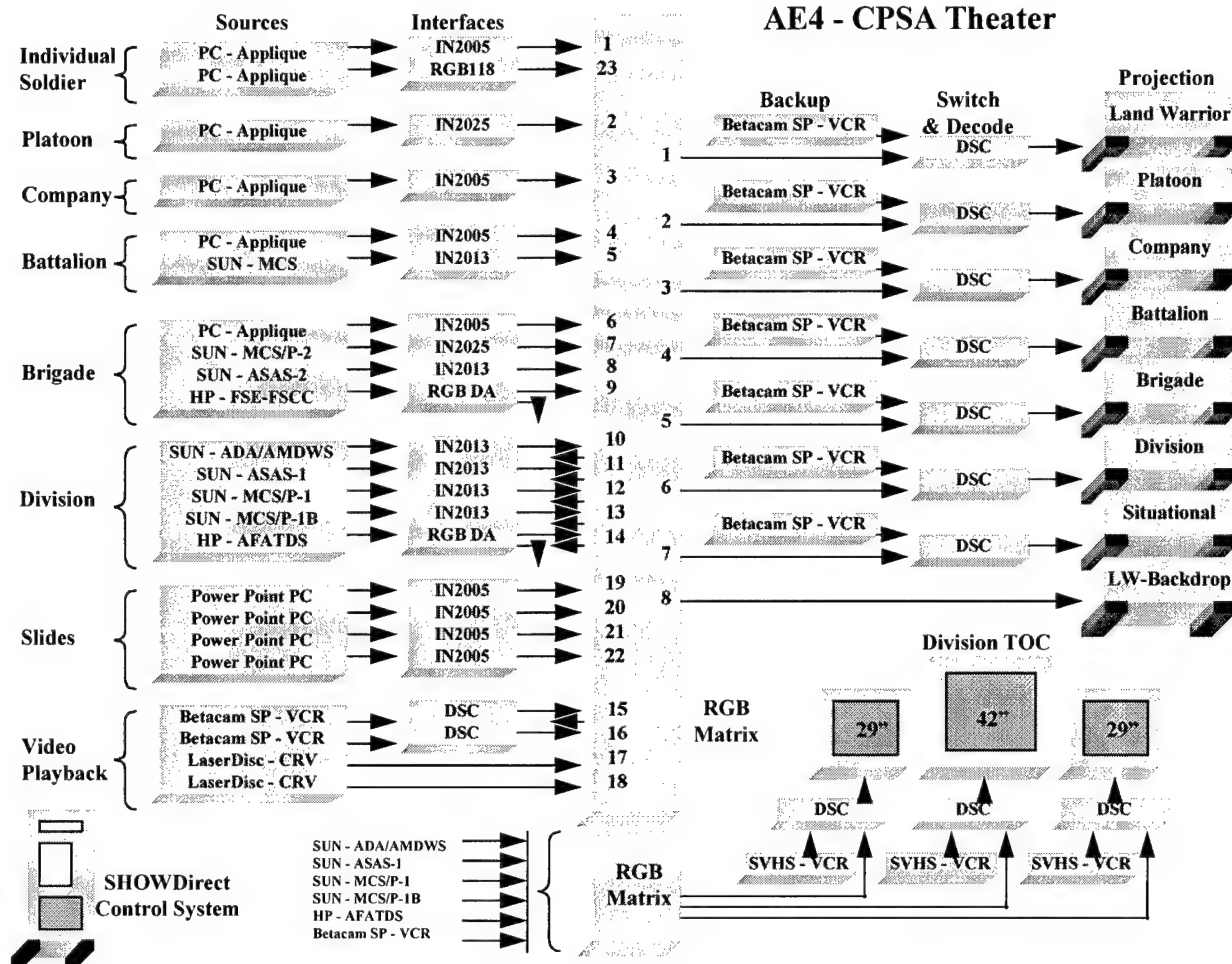

Figure 3.5.5-2 CPSAA AV Network Layout

3.6 Lessons Learned

After a group of people toured both theaters a common question that was asked was "what was stimulating the tactical systems during the CPSAA demonstration?". The demonstration did not emphasize the experiment's objectives...simulation to tactical system interfaces. There was not a comprehensive message told summarizing the Army Experiment 4 experiments. The simulation - ATCCS interfaces evaluated was never brought out in October AUSA. A recommendation would be to have brought forth the simulation and interfaces that were driving the ATCCS at the October demonstration and throughout the AE4 experiments.

3.7 Conclusions and Recommendations

- 1) The demonstration should emphasize and exploit the experiments. This could be done by starting the experiments earlier and build the criteria with the demonstration in mind. The experiments can be designed to make sure we collect the appropriate data for the demonstration. A recommendation would be to develop a campaign plan to identify and initiate the future AE's earlier in the year. This would allow an earlier sign up for participants and users.

23 April 1998

- 2) If possible the Cotillion Ballroom needs to be leased out with a minimum of 5 full days of setup and rehearsal time. The installation, integration and rehearsal had to be accomplished within the 4 days for AE4. This created 18 – 24 hour work days including short tempers and confusion. It is a premium price for the installation labor.
- 3) The AE4 presentation was organized through the ADST II contract vehicle with the exception of the multi-media section. This included the introduction video and the CD ROM. These items were contracted through CECOM to Coleman Research Corporation (CRC). The observation was that the multi-media section was not closely tied to the Experiments and therefore did not summarize the significant events that occurred throughout the program. The introduction video was also disjointed from the audio video rehearsal schedule and was not observed until the day before the Chief walk through a month later than needed. The recommendation would be to have one central chain of command that would enable the fluid integration of the presentation.
- 4) Avoid simultaneous installation/setup and rehearsal.
- 5) Recommend a more detailed construction schedule with required milestones.
- 6) The exhibit construction setup needs to have a final walk through with customer, contractor, designer and builder.
- 7) There were some missed dimensions within the exhibit that created more on site modifications that were not proposed. A new site survey drawing needs to be constructed with very accurate dimensions.

4. AE4 Planning and Management

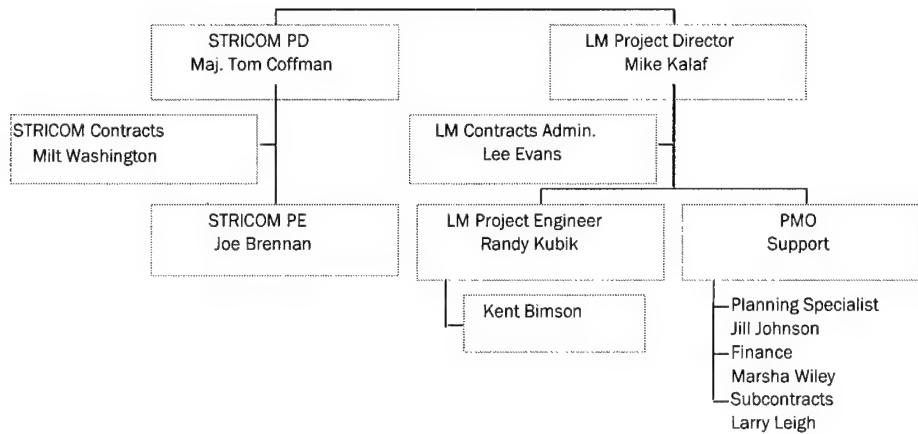

The Program Management that LMC performed was in accordance with the STRICOM Statement of Work for Army Experiment IV, (AE4), Proof of Principle, 22 May 1997, Rev 2.1. This included program management support for the attendance of In-Process Reviews (IPR's), Scenario Development meetings, Technical Interchange Meetings (TIM's), and other meetings required to support the AE4. LMC analyzed the schedule and determined problem areas as soon as possible and took corrective actions as required. STRICOM provided responsible personnel at the LMC facility throughout the AE4 program. This function enabled immediate attention to possible out of scope issues.

4.1 Program Organization

AE4's program organization is depicted in Figure 4.1-1 below.

Figure 4.1-1 AE4 Organization

23 April 1998

23 April 1998

4.2 Reporting

LMC provided written visibility into the AE4 team activities through the weekly Contractor Progress, Status, and Management Reports and the monthly Program Status Reviews.

4.2.1 Contractor Progress, Status, and Management Report

A Contractor Progress, Status, and Management Report (CPSM) was sent to the Government weekly. This report included information relating to the progress made on each task and the current status of each task.

4.2.2 Contractor Cost/Schedule Status Report

A Cost/Schedule Status Report (C/SSR) was sent to the Government monthly. This report included information relating to the current expenditures made. The format of this report was generated IAW DI-F-6010A and the accepted LMC contractor formats.

4.2.3 4.3.3 Program Management Reviews

The AE3 team supported Program Management Reviews (PMR's) as required during the conduct of the proposed efforts. PMR's were held as required by the Government.

4.2.4 Scheduling

Scheduling was updated and maintained by the LMC management team. The scheduling process enabled the customer and LMC upper management the detailed milestones to be met.

4.3 In Progress Reviews (IPR)

In preparation for AE4 there were a total of nine In Progress Reviews (IPR). Items presented at the IPR's were the following: design status; participant's status; integration and test schedules; move-in status; transportation status; and miscellaneous topics.

5. Points of Contact

The primary points of contact for this after action report are the following:

Name	Organization	Phone	email
Joe Brennan	STRICOM	407.384.3855, DSN 970	Joe_Brennan@stricom.army.mil
Mike Kalaf	Lockheed Martin Corp	407.306.4051	mike.kalaf@lmco.com

Appendix B - Scenario Documentation

Introduction

The AE4 scenario discussed in Section 3 of this document is supported by the following information in this appendix:

- Task organization and startex positions for the BLUFOR
- Task organization and startex positions for the OPFOR
- Battlefield geometry
- Routes
- Mil list

Each of these is presented below in table format.

Appendix C - Data Collection Sheets

CBS Experiment

EXPERIMENT DATA COLLECTION SHEET

Experiment: CBS Date: 8/12/97

Interface: RTM Time: 15:30

Experiment ID: CBS/RTM/R8

(Format:Exp/Interface/Mission/Run)

Objectives:

Use RT to communicate CBS red fixed wing missions flying over Patriot unit below 10k feet above ground level (AGL). RTM to communicate data to EADSIM and FAAD EO using TADIL-B report. AWACS sensor only.

Description:

Fly two SU17 Fritters in CBS from Tel C to Pat C to Tel C. Mission data sent through CBS Master Interface to RTM, which converts it to a report and routes it to EADSIM (DIS) and FAAD EO (report) simultaneously, and from there to AMDWS.

Results: Received Not Received Partially Received

Issues:

Locations:

CBS in Ft. Lewis

FAAD EO, EADSIM at WAIC

AMDWS at Ft. Leavenworth

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: CBS Date: 8/12/97 (end)

Interface: RTM Time: 16:00

Experiment ID: CBS/RTM/B8

(Format:Exp/Interface/Mission/Run)

Objectives:

Use RT to communicate CBS blue fixed wing missions flying over enemy ADA unit below 10k feet above ground level (AGL). RTM to communicate data to EADSIM and FAAD EO using TADIL-B report. AWACS sensor only.

Description:

Fly two HIP in CBS from Tel D to Patriot D to Tel D. Mission data sent through CBS Master Interface to RTM, which converts it to a F-3 report and routes it to EADSIM (DIS) and FAAD EO simultaneously, and from there to AMDWS.

Results: Received Not Received Partially Received

Issues:

1. WAIC system crashed at 10:00-10:25.
2. Ft. Leavenworth at lunch; no one monitoring AMDWS for R2A/B2A-no confirmed track data from FAAD to AMDWS (see B2A).

Locations:

CBS in Ft. Lewis

FAAD EO, EADSIM at WAIC

AMDWS at Ft. Leavenworth

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: CBS Date: 8/12/97

Interface: RTM Time: 15:00

Experiment ID: CBS/RTM/B2

(Format:Exp/Interface/Mission/Run)

Objectives:

Use RT to communicate CBS blue rotary wing missions flying over red ADA unit below 10k feet above ground level (AGL). RTM to communicate data to EADSIM through DIS protocols and FAAD EO using TADIL-B M2/M82 Track Message report. Only AWACS sensors used.

*NOTE: FDL 3 extended reports are needed for above 10k feet; FAAD EO does not read extended messages; must use TADIL-B instead, due to AWACS sensors.

Description:

Fly two AH-64 in CBS from Hawk 2 to Tel Alpha and reverse direction. Mission data sent through CBS Master Interface to RTM, which converts it to a F-3 report and routes it to EADSIM (DIS) and FAAD EO simultaneously, and from there to AMDWS.

Results: Received Not Received Partially Received

Issues:

1. See R1 mission.

Locations:

CBS in Ft. Lewis

FAAD EO, EADSIM at WAIC

AMDWS at Ft. Leavenworth

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: CBS Date: 8/12/97

Interface: RTM Time: 15:25

Experiment ID: CBS/RTM/R2/1

(Format:Exp/Interface/Mission/Run)

Objectives:

Use RT to communicate CBS red rotary wing missions flying over Hawk unit below 10k feet above ground level (AGL). RTM to communicate data to EADSIM and FAAD EO using TADIL-B M2/M82 report. Only AWACS sensors used.

Description:

Fly two HIP in CBS from Tel B to TAC B to Tel B. Mission data sent through CBS Master Interface to RTM, which converts it to a TADIL-B report and routes it to EADSIM (DIS) and FAAD EO simultaneously, and from there to CRTD and/or AMDWS.

Results: Received Not Received Partially Received

Issues:

1. FAAD EO not talking to CRTD using the F-3 reports.

Locations:

CBS in Ft. Lewis

FAAD EO, EADSIM at WAIC

CRTD and AMDWS at Ft. Leavenworth

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: CBS Date: 8/12/97 (end)

Interface: RTM Time: 16:00

Experiment ID: CBS/RTM/B8

(Format:Exp/Interface/Mission/Run)

Objectives:

Use RT to communicate CBS blue fixed wing missions flying over enemy ADA unit below 10k feet above ground level (AGL). RTM to communicate data to EADSIM and FAAD EO using TADIL-B report. AWACS sensor only.

Description:

Fly two F15E in CBS from Hawk 2 to Tel B to Hawk 2. Mission data sent through CBS Master Interface to RTM, which converts it to report and routes it to EADSIM (DIS) and FAAD EO (report) simultaneously, and from there to CRTD and to AMDWS.

Results: Received Not Received Partially Received

Issues:

Locations:

CBS in Ft. Lewis

FAAD EO, EADSIM at WAIC

CRTD and AMDWS at Ft. Leavenworth

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: CBS Date: 8/13/97 (start)

Interface: RTM Time: 09:30-10:30

Experiment ID: CBS/RTM/R2A/1

(Format:Exp/Interface/Mission/Run)

Objectives:

Use RT to communicate CBS red rotary wing missions flying over Patriot below 10k feet above ground level (AGL). RTM to communicate data to EADSIM and FAAD EO using TADIL-B report. AWACS sensor only.

Description:

Fly two HIP in CBS from Tel D to Patriot D to Tel D. Mission data sent through CBS Master Interface to RTM, which converts it to a report for the FAAD EO and routes it to EADSIM (DIS), and from there to AMDWS.

Results: Received Not Received Partially Received

Issues:

1. WAIC system crashed at 10:00-10:25.
2. Ft. Leavenworth at lunch; no one monitoring AMDWS for R2A/B2A-no confirmed track data from FAAD to AMDWS (see B2A).

Locations:

CBS in Ft. Lewis

FAAD EO, EADSIM at WAIC

AMDWS at Ft. Leavenworth

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: CBS Date: 8/13/97

Interface: RTM Time: 10:30

Experiment ID: CBS/RTM/B2A/1

(Format:Exp/Interface/Mission/Run)

Objectives:

Use RT to communicate CBS blue rotary wing missions flying over enemy ADA below 10k feet above ground level (AGL). RTM to communicate data to EADSIM and FAAD EO using TADIL-B report. AWACS sensor only.

Description:

Fly two AH-64 in CBS from Hawk 1 to Tel B to Hawk 1. Mission data sent through CBS Master Interface to RTM, which converts it to a report for FAAD EO and routes it to EADSIM (DIS) simultaneously, and from there to AMDWS.

Results: Received Not Received Partially Received

Issues:

1. Old run data (icons) interfered with tracking mission data, making AH-64 hard to see due to clutter of logged data from 8/12.
2. AH-64 classified as fixed wing aircraft due to speed ranges overlapping. AH-64 flying at 145 knots per hour. 82 meters/second is acceptable on FADD; 74 meters/second is acceptable in EADSIM.
3. Ft. Leavenworth at lunch; no one monitoring AMDWS for R2A/B2A-no confirmed track data from FAAD to AMDWS (see R2A).

Locations:

CBS in Ft. Lewis

FAAD EO, EADSIM at WAIC

AMDWS at Ft. Leavenworth

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: CBS Date: 8/13/97

Interface: RTM Time: 11:12

Experiment ID: CBS/RTM/R14

(Format:Exp/Interface/Mission/Run)

Objectives:

Use RT to communicate CBS red fixed wing missions flying over Hawk unit starting below 10k feet above ground level (AGL) and going above 10k feet AGL. RTM to communicate data to EADSIM and FAAD EO using TADIL-B report. AWACS sensor only.

Description:

Fly two SU17 Fritters in CBS from Tel C to Pat Alpha to Hawk 2 to C43, starting below 10k feet and ascending above 10k feet. Mission data sent through CBS Master Interface to RTM, which converts it to a FAAD EO report and routes it to EADSIM (DIS) simultaneously, and from there to AMDWS.

Results: Received Not Received Partially Received

Issues:

1. Fritters were not going above 10k feet: order correlation error. CBS operators were assuming top altitude of 10k feet AGL; WAIC/EADSIM were assuming 10k meters AGL.
2. F3 air tracks being sent by RTM to FAAD EO below 10k feet. Do not have tactical systems to send TADIL-B, which is being used above 10k feet (TBM) directly from RTM to AMDWS.

Locations:

CBS in Ft. Lewis

FAAD EO, EADSIM at WAIC

AMDWS at Ft. Leavenworth

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: CBS Date: 8/13/97 (end)

Interface: RTM Time: 15:22

Experiment ID: CBS/RTM/B14

(Format:Exp/Interface/Mission/Run)

Objectives:

Use RT to communicate CBS blue fixed wing missions flying over red ADA unit starting low, ascending high, and descending low again. RTM to communicate data to EADSIM and FAAD EO. AWACS sensor only.

Description:

Fly two F15E in CBS starting at 5k feet at AB1, ascending to 35k feet at Hawk 1 through Tel B and Tel D, and descending to 5k feet from Tel D to AB1. Mission data sent through CBS Master Interface to RTM, which converts it to FAAD EO report and routes it to EADSIM (DIS) and FAAD EO simultaneously, and from there to AMDWS.

Results: Received Not Received Partially Received

Issues:

1. Same problem as R14A

Locations:

CBS in Ft. Lewis

FAAD EO, EADSIM at WAIC

AMDWS at Ft. Leavenworth

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: CBS Date: 8/14/97 (start)

Interface: RTM Time: 09:30-10:15

Experiment ID: CBS/RTM/R14C

(Format:Exp/Interface/Mission/Run)

Objectives:

Use RT to communicate CBS red fixed wing missions over red territory (Tels) starting low, ascending high, and descending low again. RTM to communicate data to EADSIM and FAAD EO using TADIL-B report. Route over red territory so that aircraft are not shot down by EADSIM. This is needed for the CLCGF experiment. AWACS sensor only.

Description:

Fly five SU17 in CBS starting at 2k feet at AB to Tel B, ascending to 35k feet from Tel B to Tel C, and descending to 2k feet from Tel C to AB. Mission data sent through CBS Master Interface to RTM, which converts it to a FAAD EO report and routes it to EADSIM (DIS) simultaneously, and from there to AMDWS. Altitude check on FAAD EO and AMDWS to resolve altitude correlation problem.

Results: Received Not Received Partially Received

Issues:

1. Aircraft staying at 2k feet after Tel B; order entered wrong. CBS working correctly. Order entered as: AB--2000--B--2000--C--35000--B--2000--AB. Tracks OK.

Locations:

CBS in Ft. Lewis

FAAD EO, EADSIM at WAIC

AMDWS at Ft. Leavenworth

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: CBS Date: 8/14/97

Interface: RTM Time: NA

Experiment ID: CBS/RTM/B14A

(Format:Exp/Interface/Mission/Run)

Objectives:

Use RT to communicate CBS blue fixed wing missions over blue territory (Hawk units) starting low, ascending high, and going low again. RTM to communicate data to EADSIM and FAAD EO using TADIL-B reports.

Description:

Fly one F15E in CBS starting at 10k feet from AB1 to Hawk 1, at 40k feet from Hawk1 to Hawk 2, and at 10k feet from Hawk 2 to AB1. Mission data sent through CBS Master Interface to RTM, which converts it to a FAAD EO report and routes it to EADSIM (DIS) simultaneously, and from there to AMDWS. Altitude check on FAAD EO and AMDWS to resolve altitude correlation problem.

Results: Received Not Received Partially Received

Issues:

1. AWACS ran out of fuel in EADSIM during mission-no data capture. Repeat.

Locations:

CBS in Ft. Lewis

FAAD EO, EADSIM at WAIC

AMDWS at Ft. Leavenworth

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: CBS Date: 8/14/97

Interface: RTM Time: 10:15

Experiment ID: CBS/RTM/B14B

(Format:Exp/Interface/Mission/Run)

Objectives:

Use RT to communicate CBS blue fixed wing missions over blue territory (Hawk units) starting low, ascending high, and going low again. RTM to communicate data to EADSIM and FAAD EO using TADIL-B report. AWACS sensor only.

Description:

Fly one F15E in CBS starting at 15k feet from AB1 to Hawk 1, at 35k feet from Hawk1 to Hawk 2, and at 15k feet from Hawk 2 to AB1. Mission data sent through CBS Master Interface to RTM, which converts it to a report for FAAD EO and routes it to EADSIM simultaneously, and from there to AMDWS. Altitude check on FAAD EO and AMDWS to resolve altitude correlation problem.

Results: Received Not Received Partially Received

Issues:

1. Same as B14A: AWACS ran out of fuel in EADSIM during mission-no data capture. Repeat.

Locations:

CBS in Ft. Lewis

FAAD EO, EADSIM at WAIC

AMDWS at Ft. Leavenworth

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: CBS Date: 8/14/97

Interface: RTM Time: NA

Experiment ID: CBS/RTM/R14D

(Format:Exp/Interface/Mission/Run)

Objectives:

Use RT to communicate CBS red fixed wing missions starting low, ascending high, and descending low again. RTM to communicate data to EADSIM and FAAD EO using TADIL-B report.

Description:

Fly two SU17 in CBS starting at 2k feet from Big A to B, at 35k from B to Tel E, and at 2k from Tel E to Big A.. Mission data sent through CBS Master Interface to RTM, which converts it to a FAAD EO report and routes it to EADSIM (DIS simultaneously, and from there to AMDWS. Altitude check on FAAD EO and AMDWS to resolve altitude correlation problem.

Results: Received Not Received Partially Received

Issues:

1. Same as B14A: AWACS ran out of fuel in EADSIM during mission-no data capture. Repeat.

Locations:

CBS in Ft. Lewis

FAAD EO, EADSIM at WAIC

AMDWS at Ft. Leavenworth

23 April 1998

Experiment: CBS Date: 8/14/97
Interface: MCS SSM Time: 09:45-11:30
Experiment ID: CBS/SSM
(Format:Exp/Interface/Mission)

Objectives:

Use SSM to translate position/location data for eight maneuver units from CBS to MCS/P and compare location in simulation with location on MCS/P box. Use this data for MRCI runs of the same type to compare results.

Description:

Track the locations of eight units through seven fifteen minute location updates in CBS. The CBS units tracked include: 3/66ARM, B/3-66ARM, A/1-22MECH, B/1-22MECH, C/1-22MECH, 2BDE4, 3BDE4, and 1-10CAV.

At start time 1 (020221Z, game time), 6 units were moving and 2 were defending. By time 7, the end of the game (020353Z, game time), all units were stopped.

All eight units tracked appropriately from CBS through SSM to MCS/P. Exact grid coordinates were compared between CBS and MCS/P; no errors observed.

Results: Received Not Received Partially Received

All units tracked correctly.

Issues:

Locations:

CBS in Ft. Lewis

MCS/P in Ft. Leavenworth

23 April 1998

Experiment: CBS Date: 8/15/97
Interface: MRCI Time: 09:45-13:00
Experiment ID: CBS/MRCI
(Format:Exp/Interface/Mission)

Objectives:

Use MRCI to translate position/location data for eight maneuver units from CBS to MCS/P and compare location in simulation with location on MCS/P box. Use SSM data to compare with MRCI results.

Description:

Track the locations of eight units through seven fifteen minute location updates in CBS. The CBS units tracked include: 3/66ARM, B/3-66ARM, A/1-22MECH, B/1-22MECH, C/1-22MECH, 2BDE4, 3BDE4, and 1-10CAV.

At start time 1 (020221Z, game time), 6 units were moving and 2 were defending. By time 7, the end of the game (020353Z, game time), all units were stopped.

All eight units tracked appropriately from CBS through SSM to MCS/P. Exact grid coordinates were compared between CBS and MCS/P; no errors observed.

Results: Received Not Received Partially Received

Units received as per SSM, with one exception: see issue 2 below.

Issues:

1. The RTI machine wedged at one point because someone not involved in the experiment used it for unrelated activities-process had to be restarted.
2. The Easting location on the MCS/P box had a rounding down error. For example, D/1-22MECH showed a position of "32UQV101635" in CBS but a position of "32UQV101634" on the MCS/P box. This was consistent and is assumed to be an easily fixed algorithmic rounding error.
3. MRCI staff were able to quickly develop a capability to request unit status data and display it

Locations:

CBS in Ft. Lewis

MCS/P in Ft. Lewis

23 April 1998

CLCGF Experiment

Experiment: CLGCF Date: 27 Aug 97

Interface: TSIU Time: 15:30

Experiment ID: CLCGF / TSIU / F-59 through F-63

(Format: Experiment / Interface / Mission)

Objectives:

Send Division Level Threat Reports from EADSIM through TSIU to AMDWS (FAADC21)

Description:

F-59: TBM Pairing - screen displays line connecting Launch Point, TBM position and Impact Point

F-60: TBM Special Point - screen displays Launch Point and Impact Point marked with an X and a red TBM Warning light

F-61: TBM General Amp - screen displays an ellipse containing the Launch point and Impact Point and Amplification Window

F-62: TBM Position - screen displays missile position in reference to Launch Point and Impact Point

F-63: TBM Position Amp - screen displays TBM Amplification Window

Results: Received Not Received Partially Received

Issues:

- 1) Unclassified data could not be shown in an unclassified environment. TIBS and TRAP data would be available in a classified setting.
- 2) Logged data allows replaying of scenario and linkage for demonstrations.
- 3) AMDWS problem with TBM warning light. F-60 message should trigger a red warning light
- 4) Amount of data for AMDWS screen display caused a restart of AMDWS.
- 5) The F-60 issue shows the same logged sim data should be used for regression testing that was used for testing earlier ATCCS systems to ensure accurate handling of data.

23 April 1998

Experiment: CLGCF Date: 27 Aug 97
Interface: TSIU Time: 16:00
Experiment ID: CLCGF / TSIU / F-3
(Format: Experiment / Interface / Mission)

Objectives:

Send F-3 Track Report from EADSIM through TSIU to FAAD EO

Description:

Report should display Hostile (Red) and Friendly (Blue) Forces. Air Traffic shows Hostile or Friendly aircraft with Heading, Altitude and Speed. This information is displayed for the selected Cone of Interest only.

Results: Received Not Received Partially Received

EXPERIMENT DATA COLLECTION SHEET

Experiment: CLCGF Date: 8/28/97
Interface: TSIU Time: 13:30
Experiment ID: MCS/USMTF/S507
(Format:Exp/Interface/Mission/Run)

Objectives:

Send USMTF S507 messages from Eagle to MCS at Division, Brigade and Battalion level.

Description:

Results: Received Not Received Partially Received

Issues:

- 1) A 1-22 Mech message should not be displayed.
- 2) Check 1-10 Cav reporting at Brigade level.
- 3) Check 1-66 AR at Brigade level.
- 4) Check 4 ID, A-1-66 AR, B-1-66 AR, B-3-66 AR, C-1-66AR, D-1-66, HHC-1, HHC-1 Bde, HHC-3-66 AR icons

F-3 Report Received

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: CLCGF Date: 8/27/97

C2 System Tested: MSAC Time: 10:00

Experiment ID: CLCGF/MSAC/1

(Format:Exp/Interface/Mission/Run)

Objectives:

Run ModSAF Entity State (ES) PDU's to Mystech's casualty simulator, providing S302 free text USMTF casualty information to MSAC as a status update.

Description:

Surgical status report for MSAC is colored green, amber, black depending on number of patients to be serviced. Number can be set by user. For experiment, no patients= green; 1 patient=amber; 2 patients=black. Update rate can be set; used 15-30 second updates for experiment. Evacuation data stays green until maximum is achieved. Used logged ModSAF ES data for experiment, which contains unit damage.

Indicator icons turned green, amber, and black under stated condition.

Results: Received Not Received Partially Received

Issues:

1. Since simulation traffic and tactical messages were sent on the same network, the two had to be bridged. This combined data stream negatively impacts the C2 boxes. Need a 2 Ethernet card solution to keep the 2 data streams separated.
2. Patients do not leave beds/OR; need to modify code to let patients leave.

Locations:

MSAC, ModSAF/logged ES messages, and MCS in Orlando.

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: CLCGF Date: 8/26/97

C2 System Tested: MSAC Time: 10:00

Experiment ID: CLCGF/MSAC/Demo

(Format:Exp/Interface/Mission/Run)

Objectives:

1. Use Medical Situation Awareness and Control (MSAC) to participate in Army simulation exercise.
2. Develop casualty generator for exercise.
3. Participate in exercise from remote location.

Description:

First run was a MSAC demonstration.

MSAC was developed on the MCS beta version and is Netscape-based with Java scripts, running on Sun, Mac and PC platforms. The intent is to test MSAC medical C2 within a simulation environment at Brigade level and below. MSAC uses a common database to provide a common picture. It retrieves overlay data from ASAS and MCS/P using USMTF messages.

Four of ten medical functions have been developed in MSAC and were demonstrated successfully: medical C2, evacuation, logistics and blood, hospitalization.

The six remaining medical functions will be developed in the future, including: area medical support, combat stress, dental, lab, preventive medicine, veterinary medicine.

EXPERIMENT DATA COLLECTION SHEET

Experiment: CLCGF Date: 8/27/97

C2 System Tested: MSAC Time: 9:00

Experiment ID: CLCGF/MSAC/2

(Format:Exp/Interface/Mission/Run)

Objectives:

Observe MSAC long haul capability.

Description:

Create ModSAF Entity State (ES) PDU's in Orlando, send to MSAC long distance for parsing, observe on common database in Orlando.

Long haul test was configured as an ISDN connection between Orlando (local) and Manassas (remote) machines via modem connection. The local machine processed the DIS entity state PDU's and generated local casualty statistics. These stats were then sent to the remote machine via FTP. The remote machine parsed the casualty data and updated the remote database files. To prove visibility to the remote machine data structures, the local machine started Netscape. The local machine http pointed to Manassas and displayed the remote database information locally.

Demo successful long haul.

EXPERIMENT DATA COLLECTION SHEETS

Experiment: CLCGF Date: 9/3/97

Interface: VHMS Time: 10:00

Experiment ID: CLCGF/VHMS

(Format: Exp/Interface/Mission/Run)

Objectives:

Monitor vehicle status and update Appliqué and CSSCS.

Description:

Vehicle onboard diagnostics sends status of vehicle to VHMS. VHMS then updates Appliqué and CSSCS with information about various vehicle components. VHMS also monitors simulated vehicles from ModSAF. VHMS can be used to predict component failures based on stored statistical data.

Results: Received Not Received XPartially Received

Issues:

1. Used simulated data from "live vehicle" to remain within cost and time constraints of test.
Result: Run test again with live vehicle.
2. VHMS updated information slowly on screen. Result: VHMS currently runs on a 486 but is being ported to a Pentium for future testing.
3. VHMS only updates information on single vehicles. Result: VHMS plans on monitoring status of platoons and higher echelons in future releases.

DBBL Experiment

EXPERIMENT DATA COLLECTION SHEET

Experiment: DBBL Date: 9/4/97
Interface: Land Warrior Time: 12:30-15:00
Experiment ID: DBBL/LW/2
(Format:Exp/Interface/Run)

Objectives:

Populate the LW-IHAS view with the entities involved in the exercise, using VMF position messages from Appliqué.

Description:

Run the mission, using ModSAF, and the manned Sim's on the DIS network. Send the traffic through the Appliqué Interface, to Appliqué, populating that screen. The same entities should be passed to the LW system, from Appliqué, in VMF messages.

Results: Received Not Received Partially Received

Issues:

1. Machines not always stable, prone to crashes. LW system, when receiving messages about entities not in their host file, will crash. Appliqué unstable and crashes can result at any time. Appliqué and LW system VMF messages off by 2 bytes. Fix: LW messages were made to fill in the 8 bits with null characters when passing to appliqué. When returning the other way, LW dropped the last 8 bits from the message.

Locations:

DBBL at Ft. Benning

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: DBBL Date: 9/4/97

Interface: LW System Time: 15:00-16:00

Experiment ID: DBBL/LW/3

(Format:Exp/Interface/Run)

Objectives:

Pass report messages between LW and Appliqué.

Description:

Appliqué and LW users to create reports, and send them back and forth between the two systems.

Results: Received Not Received Partially Received

Issues:

1. Land Warrior able to send all reports to Appliqué. Byte problem still handled in Ex ID DBBL/LW/1. Appliqué only able to send Free Text messages to LW system. No other messages received correctly. Appliqué unable to generate spot reports on the MOUT terrain database. While trying to generate a spot report, Appliqué produces the error '16S not in the FA map'. Even when Appliqué generates the position itself, this error occurs. It is believed LW would be able to handle spot reports, but due to this problem, not able to test.

Locations:

DBBL in Ft. Benning

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: DBBL Date: 9/4/97

Interface: LW Time: 14:00-17:00

Experiment ID: DBBL/LW/1

(Format:Exp/Interface /Run)

Objectives:

Bring all entities up on Grafenfels database, and have them show on both Appliqué and LW system, as well as Sim's and ModSAF.

Description:

All manned Sim's and ModSAF entities are brought up on Grafenfels database. Entities are connected via the DIS net to the OSF, where more entities are placed. All entities from both sites should show on all systems.

Results: Received Not Received Partially Received

Issues:

1. LW system not able to show all entities at this time. This was fixed the following week. This experiment was postponed several times. The ARC (Army Research Center), in charge of the DIS hub, decided to update its hardware without making anyone aware first. This could have been avoided by centralizing all equipment in the experiment, or by the use of a direct connection via internet line, for example a T1 line.

Locations:

OSF at Orlando

DBBL at Ft. Benning

23 April 1998

EXPERIMENT DATA COLLECTION SHEET

Experiment: DBBL Date: 9/4/97
Interface: SVS/ODT Time: 08:30-11:30
Experiment ID: DBBL/SVS/ODT/1
(Format:Exp/Interface/Run)

Objectives:

Put all players out on MOUT Database, and test database correlation between all systems, including manned Sim's.

Description:

The mission was run, using all the entities, generated from all the systems. All Sim's should be able to see all the entities in the mission, from ModSAF generated, to other manned Sim's. Systems were brought up with Grafenfels and MOUT database and missions were run.

Results: Received Not Received Partially Received

Issues:

There were no problems found with Grafenfels database correlation with any of the systems. However, a problem existed with the MOUT database on the M2 manned Sim. Database for the M2 did not correlate with the others. When ground clamping was turned on, other entities floated in the air. When trying to view the M2 from the other manned Sim's (SVS/ODT), M2 was unable to be seen for it was under the ground. It was determined that there existed a 3 meter difference between the terrains, and only if this difference was lower in spots would you be able to see even part of the M2. But even then it was buried in the ground. A stealth was used to determine where the M2 was positioned, when it could not be seen. Fix: MOUT database for the M2 needs to be further developed, or hardware should be updated on the M2 mock-up. It was suggested the M2's current hardware configuration was the reason it could not show the database correctly.

Notes

Note 1

Red Order of Battle was generated by the TSIU for the experiment using the Battlefield Geometry message to stimulate the ASAS. The CBS experiment utilized the Firestorm system to stimulate the Intelligence portion of the TOC. It was decided for cost and schedule

23 April 1998

reasons to forego this stimulation in the CLCGF experiment. The stimulation provided by the TSIU using the Red Order of Battle messages allowed for stimulation of the ASAS without a WAN connection to the classified Firestorm system. If there is a need for the stimulation of ASAS with a low-cost, medium fidelity stimulation the TSIU was shown to be an alternative for a collective training setting.

Note 2

An adjunct to the ASAS stimulation provided by the TSIU was the Moving Target Indicator (MTI) normally provided by JSTARS feeds. The MTI message was generated utilizing the Aggregate State PDU's from Eagle and sending these messages to ASAS. An alternative to utilizing the Eagle as the simulation engine is the use of a JSTARS simulation dedicated to reading entity and aggregate states to generate an MTI message. The major reason for not utilizing a dedicated JSTARS simulation was that they generally operate in a classified mode. The Army Experiment 4 was conducted completely unclassified.

Note 3

The TACFIRE message was not simulated during the Army Experiment 4. We did not have access to the TAFSIM/PIU for the experiment. The D & SA Battle Lab at Ft. Sill utilizes these simulation systems to interact the AFATDS with simulation scenarios. The systems were not available for the Army Experiment 4. As noted later a call for fire message was generated via Applique, but full interaction with AFATDS was not accomplished during AE4.

Note 4

The NBC sensor system was generated by the PEGEM system at the ARC in Huntsville and connected to the AE4 laboratory via normal dial-up phone line via 56KB modem. The NBC sensor sent DIS pdu's which the TSIU interpreted and sent NBC messages to the Maneuver Control Station and Applique.

Note 5

The low altitude air picture was generated using DIS entity state PDU's which the TSIU read and then using the information contained therein created FDL messages which stimulated the FAAD EO system which in turn alerted the AMDWS. This simulation/stimulation allows for the training of FAADC2I operators and collective training of TOC staff. During the experiment it was necessary to connect the ABCS systems with the simulation network traffic during the testing of the MSAC system. It was noted that the FAAD EO systems did not operate properly when this network configuration was in place. There was not time to ascertain the exact cause of the problem caused by the coexistence of simulation and tactical

23 April 1998

traffic on the same LAN. The FAAD EO systems would not start when the hardware was connected to the simulation LAN. This was the only problem experienced when connecting simulation and tactical systems.

Note 6

Spot reports were generated in a variety of methods during the AE4 CLCGF experiment. The CFOR ModSAF system was configured to generate messages from ModSAF simulated entities to associated Applique systems on the network. The modeling of sensors was accomplished in the CFOR ModSAF simulation. The Mitre Applique interface utilized the CCSIL messages from CFOR ModSAF to create interactions between Applique and ModSAF entities. When a spot report was generated from an Applique the Mitre Applique interface would generate a CCSIL message which would cause the ModSAF entities to respond. The TSIU interacted with these same CCSIL messages. The use of the CFOR ModSAF, Mitre Applique Interface or TSIU to interact with simulation allows tactical systems have interactions between tactical systems and simulations with human interventions to effect behaviors of simulated entities.

Note 7

Friendly position reports were generated by various systems. The TSIU utilized the DIS Entity and Aggregate PDU data to generate Blue force positions to all echelons of MCS systems and all levels of Applique systems. The Blue picture was continuously updated on tactical systems based on simulation data. The Mitre Applique Interface read DIS Entity State data and generated position reports utilizing the CCSIL message sets which interface with ModSAF. Utilizing the CCSIL messages allows for the modeling of behaviors and propagation of signals in the simulation systems. The VHMS utilized DIS data connected via dial-up connection to a vehicle on a range at Eglin AFB. This position data was used to display the position data of the live tank on the Applique screen.

Note 8

The VHMS read simulation traffic (Entity States and detonation PDU's) and generated vehicle status messages to the Applique. The updated fuel/weapons/vehicle status information was forwarded from the live vehicle to the Applique. The plan originally called for the information to be forwarded from the Applique system to the CSSCS logistics tactical system. Because of problems with software versions on the tactical systems this connection was not integrated fully. Due to time constraints the connection of tactical systems and Applique were accomplished after the test of the VHMS.

23 April 1998

Note 9

The Mitre Applique Interface and CFOR ModSAF were the only interfaces, which dealt with FRAGO messages. Using the modeling available with the CCSIL interface allows simulations to cause changes in behaviors of simulated entities without human intervention. The setup of the ModSAF creates realistic radio networks, which can be utilized to generate CCSIL messages, which can direct simulations to change behaviors. The FRAGO was tightly controlled so that the computers could understand the directions contained in the message.

Note 10

The MSAC system read DIS PDU's and generated casualty information for the MCS system. The architecture of the MSAC interface called for the addition of software to the actual MCS. This required that the MSAC system (MCS) tactical system be put on the same LAN as the simulated entities. This interface read DIS data and generated casualty reporting and allowed the operator to deploy medical assistance to the battlefield. The problems with placing the tactical and simulation systems on the same LAN are described above. No adverse conditions were caused by placing MSAC software on the MCS platform, although it should be noted that if software is added to the tactical systems any problems, which arise, are more difficult to resolve.

Note 11

OPORD messages were generated by the Mitre Applique interface and CFOR ModSAF system. The limitations noted in sending FRAGO messages applied also when generating OPOD messages.

Note 12

Call for fire messages were generated by the Applique and interfaced with simulation using the TSIU and Mitre Applique interface. Both systems interpreted the CFF message from the Applique and translated the message to CCSIL which were sent to the CFOR ModSAF system. This interface allowed for the shooting of artillery without human intervention. Modeling of correct rounds and realistic firing events were accomplished on the simulation system.

23 April 1998

Appendix G - AE4 Residual Products

Products with Tangible Benefit

The AE4 experiments produced an impressive number of tangible deliverables. Six significant examples are discussed in the paragraphs below, followed by a table summarizing the remaining products. Of these six, four offer new capabilities with the potential to immediately impact the way the Army conducts Situational Awareness training.

1. The RTM used to link CBS to EADSIM and EADSIM to the FAADC2 systems. This capability was developed for assessment in AE4 and the results of the CBS Experiment show that it has the potential to immediately improve the ability of air defense soldiers to train in the planning, employment, and engagement of air defense weapon systems in the context of a CBS exercise. The RTM, together with EADSIM, significantly increased the level of resolution at which air defense events were played over CBS. As a result, it was able to realistically stimulate both AMDWS and CRTD with aircraft and missile tracks and engagement results. This capability would provide a much more realistic training environment for air defense soldiers than is currently supported in CBS exercises. Details of RTM performance are contained in Chapter 3.

2. The TSIU was used to link both Eagle and ModSAF to Appliqué and the ATCCS systems. Although the TSIU had been in use before AE4, the number and type of tactical messages that it is capable of handling was increased for AE4. AE4 also marked the first time that the TSIU had operated on CCSIL messages in the latest release of ModSAF (development version STOW 97) and the first time the TSIU had been used to send fire commands to artillery units within ModSAF. During AE4, the TSIU proved to be a robust and reliable interface between ModSAF and the ATCCS and Appliqué systems. It was also able to pass information to ATCCS on units played at the aggregate level in Eagle and "ghosted" in ModSAF. Details of TSIU's performance and capabilities are contained in Chapter 4.

3. The Soldier Visualization Station (SVS). The SVS was a new system for AE4 that was demonstrated in the DBBL Experiment. The SVS is a PC-based, commercial, off-the shelf product that is one of the latest developments in Individual Combatant (IC) virtual simulators. The SVS provides a realistic training capability for military operations in urban terrain (MOUT) and other critical IC tasks. It provided a good illustration of how PC-based equipment can provide acceptable virtual (human-in-the-loop) simulation at a significantly lower cost than previously realized. When compared to existing, UNIX-based systems, SVS

23 April 1998

provides about one-fourth the visual resolution (640X480 versus 1280X1024) at about the same frame rate on the same database for about one-twentieth the cost. This makes it feasible to develop squad and platoon sized virtual training systems for dismounted soldiers. SVS details are provided in Chapter 5.

4. A link between the Land Warrior system and Appliqué. While planning for the DBBL portion of the Experiment, it was discovered that Land Warrior and Appliqué had not been linked and, therefore, could not exchange situational awareness data. This means, for example, that the position and status of a dismounted soldier with the Land Warrior system could not be displayed on the Appliqué system in the squad leader or platoon leader's fighting vehicle. Although this seemed to be an obvious requirement, it had not been funded under either program. AE4 provided funding and a context in which to develop and assess such a linkage. Note that this link is between two real-world C4I systems and has applications both for training and for actual operations.

5. The MITRE ModSAF Appliqué Interface (MMAI). The **MMAI** provided a two way VMF interface between Appliqué systems and the ModSAF simulation. The MMAI was actually a federation of simulations and interfaces based on the High Level Architecture (HLA). The MMAI development effort demonstrated the potential of the HLA to provide a framework for integrating C4I systems with simulations. The baseline capability was extended by introducing realistic communications effects. Assessment of the MMAI was limited due to resource constraints. However, the MMAI did demonstrate, among other things, an approach to provide a realistic simulation of communications effects for Situational Awareness training.

In addition to these four products, AE4 produced two significant products that could directly benefit Situational Awareness training, but that would require more development to do so. Nevertheless, they offer significant potential for improving the Army's training capabilities.

1. The Medical Situational Awareness and Control (MSAC) system added two new capabilities to the systems examined during the CLCGF Experiment: the simulation of personnel casualties using ModSAF PDU's, and support for a unit's medical staff in the management of medical care in combat. ModSAF, with the MSAC software added, was the only simulation examined in AE4 capable of reporting realistic numbers and types of casualties based on combat action. In AE4 these reports were received on a Beta version MCS workstation to which had been added the MSAC medical command and control module. The combination of casualty simulation and medical support management demonstrated by MSAC has the potential to greatly increase the training opportunities for medical support personnel.

23 April 1998

2. The Vehicle Health Monitoring System (VHMS) is intended to allow maintenance personnel to gain Situational Awareness of the maintenance status of every vehicle in their unit. In its final form VHMS will comprise a monitoring system on the vehicle and a maintenance module on the CSSCS workstation. In the CLCGF Experiment both a live maintenance module (on a tank located at Eglin Air Force Base) and simulated maintenance modules (using VHMS software together with ModSAF) were used to feed current maintenance status to CSSCS via Appliqué. Although problems were encountered with the Appliqué to CSSCS link, VHMS successfully demonstrated a maintenance concept with potential applications in both training and real-world operations.

The remaining tangible results are summarized in Table A-1 below. Each result is placed into a category based on its support for the development of doctrine, training, leader development, and organization, material or soldier systems (DTLOMS).

Table F-1 Tangible Products from AE4.

Category	Tangible Results	Description and Potential Uses
Doctrine	There were no doctrinal or concept issues examined during AE4 but many residuals can be used to examine doctrine and concepts in future experiments.	
Training	Integration of Land Warrior into SVS	Allows Land Warrior to operate in a simulation with SVS
Training	Terrain Database for MOUT Site into SIMNET and Appliqué	Allows SVS and M2 Bradley with Appliqué to operate and communicate in the same simulation scenario
Training	ModSAF-Appliqué Interface with Realistic Communications (MITRE Corporation Internal R&D Initiative)	Incorporation of realistic communications into simulation-driven exercises in order to train and experiment with the impacts of terrain and other factors affecting digitized operations
Training/ Materiel	Medical Situational Awareness and Control (MSAC) software development and MCS integration	Provide training for medical personnel, staff and commanders in the planning for and control of medical support assets in a simulation-driven exercise.
Training/ Materiel	Vehicle Health Monitoring System (VHMS) development and CSSCS/Appliqué integration	Provide training for logistics personnel in managing and responding to vehicle damage and maintenance problems in a simulation-driven exercise.
Leader Development	Usable C4I/Simulation Architecture	Base for Digital Reaction Courses, particularly in the WarLab at Fort Leavenworth and at

23 April 1998

Category	Tangible Results	Description and Potential Uses
		officer training centers such as Fort Knox and Fort Benning
Organizations	There were no organizational change issues examined during AE4. However, many residuals can be used to assist in the examination of organizational structures in future experiments, particularly in the Tactical Decision-Making Process experiments at Fort Leavenworth BCBL (L)), in the brigade and below staff organization (Fort Knox MMBL) and in Tactics, Techniques and Procedures for Army XXI being developed at Training Centers.	
Materiel	Land Warrior-to-Appliqué Interface software	The development of a link between the Land Warrior information system and Appliqué, allowing the individual soldier system to become a part of the FBCB2 network
Materiel	Medical Situational Awareness and Control (MSAC) software development and MCS integration	Provide digitized system for medical personnel, staff and commanders for the planning and control of medical support assets in a tactical environment.
Materiel	Vehicle Health Monitoring System (VHMS) development and CSSCS/Appliqué integration	Provide digitized system for logistics personnel in managing and responding to vehicle damage and maintenance problems in a tactical environment
Materiel	Air and Missile Defense Work Station (AMDWS) development	Follow on system to the Forward Area Air Defense Command and Control and Intelligence (FAADC2I) system that is a part of ATCCS
Materiel	Simulation Interface Unit (SIU) development	During AE4 the SIU version that was designed to work with the newest versions of ModSAF and Eagle simulations was placed into service and software problems were corrected
Soldier Systems	N/A	

23 April 1998

Products with Intangible Benefit

Some of the most significant results of the AE4 program were in the form of intangible benefits. The AE4 experiments were monitored by a number of military and civilian subject matter experts whose observations make up a large part of this report. The backgrounds of these observers include enlisted system operators and staff officers from the 4ID, technical representatives of the PEOC3S, civilian analysts and technicians from government agencies, civilian contractors, and Federally Funded Research and Development Center (FFRDC) staff. All key observers as a check on correctness and objectivity reviewed a draft of this report. Table F-2 provides a summary of intangible benefits from the AE4 experiments.

Table F-2 Intangible Benefits from AE4

Category	Intangible Benefit	Description and Potential Uses
Doctrine	Not applicable	
Training	MRCI: Knowledge about how MRCI works as an interface between CBS & MCS	Design feedback to MRCI developers and a roadmap for future development
Training	FIRESTORM: Knowledge and experience in using it in a CBS confederation over a distributed network	Decisions regarding further development and methods for incorporating it into both distributed and on-site simulations and exercises.
Leader Development	Not applicable	
Organizations	Not applicable	
Material	Battle Lab Integrated Concept Emulation Program (BICEP) "experiment" simulation/C4I architecture, structure, and scenario	AE4 CLCGF experiment structure and scenario will be used in BICEP simulator demonstration during the Division AWE to examine aviation capabilities and force structure
Materiel	ATCCS: Information regarding local networking, connectivity and use	Experiences of system technicians and comments from system operators during the experiments can assist in development and product improvement
Materiel	Simulations in general	Several development teams (including WARSIM) are interested in capturing the lessons learned from AE4 to assist in development of their products
Soldier Systems	Not applicable	

23 April 1998

Perhaps the greatest value of AE4 is in the intangible residuals - the knowledge and lessons learned gained through documented observations by subject matter experts. If properly disseminated, these residuals can directly support ongoing Army programs, such as WARSIM, that are focused on developing simulation/interface systems for training.

Appendix J - Organization Structure

ORGANIZATION	FUNCTION	
TRADOC	Sponsor	
STRICOM	ADST II Agency	
LMIS	ADST II Contractor	
LMSG	Site Support, Materials, Facilities, DBase Dev, Eagle, ModSAF	
SAIC	Personnel Support	
TASC	Personnel Support	
AEgis	Personnel Support	
Reality By Design	SVS, LWTB Support	
Hughes	LW System	
Cubic Applications	Personnel Support	
Image Technical Support	Audio Video Design, Supply & Support	
Ulf Helgesson	Exhibit Designer	
Exhibit Crafts	Exhibit Builder, Show Support, Storage	
DBBL	LWTB Support	
US Army Space & Missile Defense Command		
Battle Command Battle Lab Ft. Huachuca	FIRESTORM	

23 April 1998

ORGANIZATION	FUNCTION
NSC	WARLAB Facility, Resources
EPG	SSIMs, Facilities, Resources
PEOC3S	ATCCS, Resources
TRW	AMDWS, Applique
PM Air Defense Com & Control System	ATCCS Support
PM Intel Fusion	ATCCS Support
USAMRMC	Tele-Med
Mystech	Tele-Med Support (MSAC)
MICOM	Pass Through - CRC
CRC	CD ROM
Maguire-Reeder	Introduction Theater Video, Multi-Media
CECOM	Pass Through - Mitre
Mitre	TRADOC Technical Advisor
SMDC	TSIU, RTM, Simulation Support
CRC	TSIU & Sim Support
Booze-Allen Hamilton	RTM
Mevatec	PEGEM Sim
Avn & Missile Com	VHMS Development & Support
GSA	MRCI for CBS
SAIC	

13 February 1998

Appendix K - GLOSSARY

AAR	After Action Report
ABCS	Army Battle Command Systems
ACR	Advanced Concepts Requirements
A/C	Air Conditioning
ADST	Advanced Distributed Simulation Technology
AE3	Army Experiment III
AE4	Army Experiment IV
AMC	Army Material Command
AMP	Ampere
AO	Area of Operations
AFATDS	Advanced Field Artillery Tactical Data System
ASAS	All Source Analysis System
AT&T	American Telegraph and Telephone Company
ATCCS	Army Tactical Command and Control System
AUSA	Association of the United States Army
BDS-D	Battlefield Distributed Simulation - Developmental
BTU	British Thermal Unit
C2	Command and Control
C2V	Command and Control Vehicle
C4I	Command, Control, Communications, Computers & Intelligence
CBS	Corps Battle Simulation
CLCGF	Corps Level Computer Generated Forces
CD-ROM	Compact Disc - Read Only Memory.
CDRL	Contract Data Requirements List
CIG	Computer Image Generator

23 April 1998

CFOR	Command Forces
Ckts	Circuits
CPU	Computer Processing Unit
C/SSR	Cost/Schedule Status Report
DBBL	Dismounted Battlespace Battle Lab
DO	Delivery Order
DED	Dynamic Element Database
DI	Dismounted Infantry
DIS	Distributed Interactive Simulation
Div	Division
DMA	Defense Mapping Agency
DOS	Disk Operating System
DSBL	Depth and Simultaneous Attack Battle Lab
DSI	Defense Simulation Internet
ECI	Exhibit Crafts Inc.
FAA	Forward Assembly Area
FIRESTORM	Federation of Intelligence, Reconnaissance, Surveillance and Targeting, Operations, and Research Models
FAS	Feasibility Analysis Study
FSE	Fire Support Element
GES	Greyhound Exposition Services
GFE	Government Furnished Equipment
GFI	Government Furnished Information
HAI	Houston Associates, Inc
HQ	Headquarters
HVAC	Heating Ventilation Air Conditioning
IAW	In Accordance With
ID	Identification

23 April 1998

IDO	IRIX Development Option
IDREN	Interim Defense Research Engineering Network
IG	Image Generator
IP	Internet Protocol
IPR	In-Progress Review
ISDN	Integrated Services Digital Network
ITSEC	Interservice/Industry Training Systems Education Conference
ITS	Image Technical Services
JVL	Joint Virtual Laboratory
Kbits	Kilobits
Kbps	Kilobit per second
Kbits/Sec	Kilobits per second
KVA	Kilo Volt-Ampere
LAM-TF	Louisiana Maneuvers - Task Force
LAN	Local Area Network
LANDSAT	Land Satellite
LHN	Long Haul Network
LMC	Lockheed-Martin Corp
LOE	Level of effort
Log	Logistics
LSTAT	Life Support for Trauma And Transport
LTTS	Loral Training and Technical Services
LWSE	Land Warrior Simulation Extension
LWTB	Land Warrior Test Bed
M1	Abrams tank
MAC	Macintosh
MMAI	MITRE ModSAF Appliqué Interface
MAX	Maximum

23 April 1998

MB	MegaByte
Mb	Megabits
Mb/sec	Megabits per second
MCS	Maneuver Control System
MDBIC	Missile Defense Battle Integration Center
MHZ	Mega Hertz
MICOM	Missile Command
MLRS	Multiple-Launch Rocket System
MM3V	Mobile Medical Mentoring Vehicle
ModSAF	Modular Semi-Automated Forces
MRCI	Modular Reconfigurable C4I Interface
MPRS	Mission Planning Rehearsal System
MSAC	Medical Situational Awareness and Control
MSI	Multi-Spectral Imagery
NAI/TAI	Names Area of Interest/Target Area of Interest
NATO	North Atlantic Treaty Organization
NEMA	National Electrical Manufacturers Association
NFS	Network File System
NPGS	Naval Post-Graduate School
NPSNET	Naval Post-Graduate School Network
NTC	National Training Center
OCs	Observers/Controllers
ODIN	Extension of the SIMNET SAF
OPFOR	Operational Forces
OSF	Operational Support Facility
OTW	Out The Window
PC	Personal Computer
PDU	Protocol Data Unit

23 April 1998

PMCAAN	Program Manager, Combined Arms Assessment Network
PMO	Program Management Office
PMR	Program Management Review
POC	Point of Contact
PSM	Personnel Status Monitor
PVD	Plan View Display
RDA	Research Development & Acquisition
Res	Resolution
RF	Radio Frequency
RTM	Run Time Manager
SAF	Semi-Automated Forces
SAFOR	Semi-Automated Forces
SAT	Satellite; short for Satellite Command
SATCOM	Satellite Command
SCSI	Small Computer Standard Interface
sec	Seconds
SGI	Silicon Graphics, Inc.
SHAPE	Supreme Headquarters Allied Powers Europe
SIK	Sikorsky Aircraft Company
Sim	Simulator
SIMITAR	Simulation In Training for Advanced Readiness
SIMM	Single Integrated Memory Module
SIMNET	Simulation Network
SME	Subject Matter Expert
SOF	Special Operations Force
STRICOM	Simulation Training and Instrumentation Command
SVS	Soldier Visualization System
SWH	Sheraton Washington Hotel

23 April 1998

T1	Digital T-carrier service
TBD	To Be Determined
TDY	Temporary Duty
TEL	Transporter/Erector/Launcher
TEMO	Training, Exercise & Military Operations
TI	Texas Instruments
TIES	Terrain Information Extraction System
TOC	Tactical Operations Center
TR	Technical Report
TRANSCOM	U.S. Army Transportation Command
TSIU	Tactical Simulation Interface Unit
UAV	Unmanned air Vehicle
UDLP	United Defense Limited Partnership
USACOM	U.S. Army Command
USAF	United States Air Force
VCR	Video Camera Recorder
VHMS	Vehicle Health Monitoring System
VME	Virtual Memory Extension
VP	Virtual Prototype
